

LING 331

Text Processing for Linguists

Week 7

—

Jupyter and Basic Python 3

Today: Code Review! A3 and A4

- Choose a round-robin cycle
 - A checks B's, B checks C's, C checks A's
- Start by going to your partner's directory and doing:

```
cp assignment4.py assignment4_peer.py
```
- Edit `assignment4_peer.py`, make comments like I do:

```
### [AE] This is great!
```
- ~30 mins review, ~15 mins discussion

Today: Code Review!

- Questions to ask yourself:
 - Does this work?
 - Do I understand why it works?
 - What could be better? (style, efficiency, readability)
 - Compare to our grading and/or solutions

Jupyter! - Live Assignment 5 Demo

Basic steps:

- `wget` assignment link into a Quest `assignment5` directory
- Do `unzip assignment.zip`
- Go to <https://jupyter.questanalytics.northwestern.edu>
(must be on NU VPN)
- Navigate to your `assignment5` dir
and open 'Assignment 5.ipynb'

Writing Files

- With a file path as a str `f`, we've seen `open(f)`
- `open` takes a mode argument which explains how to open it
 - Actions:
 - 'r' to read (default) like Unix <
 - 'w' to write (to a new file) like Unix >
 - 'a' to append (add to existing file) like Unix >>
 - Formats:
 - 't' for text (default)
 - 'b' for binary

**action and format
can both be included
and are both optional**

Writing Files

- Write using the `.write()` method on a file object.
- Say given a Counter of word counts in some text

```
file = open('output.txt', 'w') # creates/overwrites
for word in counts:
    line = "{} , {}".format(word, counts[word])
    file.write(line + '\n') # must be str
file.close() # makes sure everything is written
```

- Unlike `print`, `.write()` only takes one argument, a string

JSON (Javascript String Object Notation)

provides a way to save objects as text

- Say given our dictionary variable `cmudict`

```
import json
json.dump(cmudict, open('cmudict.json', 'wt'))
```

Later, or in another script:

```
cmudict = json.load(open('cmudict.json', 'rt'))
```

JSON (Javascript String Object Notation)

provides a way to save objects as text

- Can also just convert them to strings:

```
json.dumps(cmudict)
```

```
'{"3-D": ["TH R IY1 D IY2"], "3D": ["TH R IY1 D IY2"], "A":  
["AH0", "EY1"], "A\\'S": ["EY1 Z"], "A.": ["EY1"], "A\\.\'S": ["EY1  
Z"], "A.S": ["EY1 Z"], "A42128": ["EY1 F AO1 R T UW1 W AH1 N T  
UW1 EY1 T"], "AA": ["EY2 EY1"], "AAA": ["T R IH2 P AH0 L EY1"],  
"AABERG": ["AA1 B ER0 G"], "AACHEN": ["AA1 K AH0 N"], "AACHENER":  
["AA1 K AH0 N ER0"], "AAH": ["AA1"], ...
```

Pickle

provides a way to save objects in binary

- Say given our dictionary variable `cmudict`

```
import pickle
pickle.dump(cmudict, open('cmudict.pkl', 'wb'))
```

Later, or in another script:

```
cmudict = pickle.load(open('cmudict.pkl', 'rb'))
```

JSON

vs. Pickle

- Saved as plaintext
(easy to open and look at)
- Can even be edited directly
outside python (carefully)
- Compatible with many other
programming langs
- Some objects are not JSON
serializable, e.g. set

- Not human readable
- Python-only
- Slower (generally)
- But works on
almost any object

Takeaway

Use JSON unless you can't.

FYI, Jupyter notebooks are in JSON format!
