1 **Abstract**

2
3 Modern economic growth started in the West in the early nineteenth century. This survey
4 discusses the precise connection between the Industrial Revolution and the beginnings
5 of growth, and connects it to the intellectual and economic factors underlying the growth
6 of useful knowledge. The connections between science, technology and human capital
7 are re-examined, and the role of the eighteenth century Enlightenment in bringing about
8 modern growth is highlighted. Specifically, the paper argues that the Enlightenment
9 changed the agenda of scientific research and deepened the connections between theory
10 and practice.

9 1. Introduction 9

10 10
11 As every economist knows, the modern era is the era of economic growth. In the past 11
12 two centuries, measures of output per capita have increased dramatically and in a sus- 12
13 tained manner, in a way they had never done before. It seems by now a consensus to term 13
14 the start of this phenomenon “the Industrial Revolution”, although it is somewhat in dis- 14
15 pute what precisely is meant by that term [Mokyr (1998b)]. In the past two decades an 15
16 enormous literature has emerged to explain this phenomenon. A large number of “deep” 16
17 questions have emerged which this literature has tried to answer. Below I list the most 17
18 pertinent of these questions and in the subsequent pages, I shall make an attempt to 18
19 answer them. 19
20 20

- 21 1. What explains the *location* of the Industrial Revolution (in Europe as opposed to 21
22 the rest of the world, in Britain as opposed to the rest of Europe, in certain regions 22
23 of Britain as opposed to others). What role did geography play in determining the 23
24 main parameters of the Industrial Revolution? 24
- 25 2. What explains the *timing* of the Industrial Revolution in the last third of the eigh- 25
26 teenth century (though the full swing of economic growth did not really start until 26
27 after 1815)? Could it have started in the middle ages or in classical antiquity? 27
- 28 3. Is sustained economic growth and continuous change the “normal” state of the 28
29 economy, unless it is blocked by specific “barriers to riches” or is the stationary 29
30 state the normal condition, and the experience of the past 200 years is truly a 30
31 revolutionary regime change? 31
- 32 4. What was the role of technology in the origins of the Industrial Revolution and 32
33 the subsequent evolution of the more dynamic economies in which rapid growth 33
34 became the norm? 34
- 35 5. What was the relation between demographic behavior (and specifically the fall in 35
36 mortality after 1750 and the subsequent decline in fertility and shift toward fewer 36
37 but higher-quality children) in bringing about and sustaining modern economic 37
38 growth? 38
- 39 6. What was the role of institutions (in the widest sense of the word) in bringing 39
40 about modern economic growth, and to what extent can we separate it from other 40
41 factors such as technology and factor accumulation? 41
- 42 7. To what extent is modern growth due to “culture”, that is, intellectual factors re- 42
43 garding beliefs, attitudes, and preferences? Does culture normally adapt to the 43

- 1 economic environment, or can one discern autonomous cultural changes that 1
2 shaped the economy? 2
3 8. Did the “Great Divergence” really start only in the eighteenth century, and until 3
4 then the economic performance and potential of occident and the orient were 4
5 comparable, or can signs of the divergence be dated to the renaissance or even 5
6 the middle ages? 6
7 9. Was the Industrial Revolution “inevitable” in the sense that the economies a thou- 7
8 sand years earlier already contained the seeds of modern economic growth that 8
9 inexorably had to sprout and bring it about? 9
10 10. What was the exact role of human capital, through formal education or other 10
11 forms, in bringing about modern economic growth? 11
12
13

14 **2. Technology and economic growth** 14

15
16 Economists have become accustomed to associate long-term economic growth with 16
17 technological progress; it is deeply embedded in the main message of the Solow- 17
18 inspired growth models, which treated technological change as exogenous, and even 18
19 more so in the endogenous growth models.¹ An earlier growth literature regarded tech- 19
20 nology as a *deus ex machina* that somehow made productivity grow miraculously a little 20
21 each year. The more modern literature views it as being produced within the system by 21
22 the rational and purposeful application of research and development and the growth of 22
23 complementary human and physical capital. The historical reality inevitably finds itself 23
24 somewhere in between those two poles, and what is interesting above all is the shift of 24
25 the economies of the West in that continuum. Whatever the case may be, technology is 25
26 central to the dynamic of the economy in the past two centuries. Many scholars believe 26
27 that people are inherently innovative and that if only the circumstances are right (the 27
28 exact nature of these conditions differs from scholar to scholar), technological progress 28
29 is almost guaranteed. This somewhat heroic assumption is shared by scholars as diverse 29
30 as Robert Lucas and Eric L. Jones, yet it seems at variance with the historical record 30
31 before the Industrial Revolution. That record is that despite many significant, even path- 31
32 breaking innovations in many societies since the start of written history, it has not really 32
33 been a major factor in economic growth, such as it was, before the Industrial Revolution. 33

34 Instead, economic historians studying earlier periods have come to realize that tech- 34
35 nology was less important than institutional change in explaining pre-modern episodes 35
36 of economic growth. It is an easy exercise to point to the many virtues of “Smithian 36
37 Growth”, the increase in economic output due to commercial progress (as opposed to 37
38 technological progress). Better markets, in which agents could specialize according to 38
39

40
41
42
43 ¹ The opening line of the standard textbook in the area states that the “most basic proposition of growth 41
42 theory is that in order to sustain a positive growth rate of output per capita in the long run, there must be 42
43 continual advances in technological knowledge” [Aghion and Howitt (1997, p. 11)]. 43

1 their comparative advantage and take full advantage of economies of scale, and in which 1
2 enhanced competition would stimulate allocative efficiency and the adoption of best- 2
3 practice technology could generate growth sustainable for decades and even centuries. 3
4 Even with no changes whatsoever in technology, economies can grow in the presence 4
5 of peace, law and order, improved communications and trust, the introduction of money 5
6 and credit, enforceable and secure property rights, and similar institutional improve- 6
7 ments [Greif (2003)]. Similarly, better institutions can lead to improved allocation of 7
8 resources: law and order and improved security can and will encourage productive in- 8
9 vestment, reduce the waste of talent on rent-seeking and the manipulation of power for 9
10 the purposes of redistribution [North (1990), Shleifer and Vishny (1998) and Baumol 10
11 (2002)]. Tolerance for productive “service minorities” who lubricated the wheels of 11
12 commerce (Syrians, Jews and many others) played important roles in the emergence 12
13 of commerce and credit. Economic history before 1750 is primarily about this kind 13
14 of growth. The wealth of Imperial Rome and the flourishing of the medieval Italian 14
15 and Flemish cities, to pick just a few examples, were based above all on commercial 15
16 progress, sometimes referred to as “Smithian Growth”.² 16

17 It is usually assumed by economists that sustained economic growth is a recent 17
18 phenomenon simply because if modern rates of growth had been sustained, a simple 18
19 backward projection suggests that income in 1500 or in 1000 would have been absurdly 19
20 low.³ Clearly, growth at the rates we have gotten used to in the twentieth century are 20
21 unthinkable in the long run. Yet it is equally implausible to think that just because 21
22 growth was slower, there was *none* of it – after all, there is a lot of time in the long 22
23 run. One does not have to fully subscribe to Graeme Snooks’ use of Domesday book 23
24 and Gregory King’s numbers 600 years later to accept his view that by 1688 the British 24
25 economy was very different indeed from what it had been at the time of William the 25
26 Conqueror. Adam Smith had no doubt that “the annual produce of the land and labour 26
27 of England . . . is certainly much greater than it was a little more than century ago at 27
28 the restoration of Charles II (1660) . . . and [it] was certainly much greater at the restora- 28
29 tion than we can suppose it to have been a hundred years before” [Smith (1976 [1776], 29
30 pp. 365–366)].⁴ On the eve of the Industrial Revolution, large parts of Europe and some 30
31

32
33 ² To be sure, much of this commerce was closely related to the manufacturing bases of the surrounding area, 33
34 such as woolen cloth production in Flanders or the production of glass in Venice. 34

35 ³ For instance, income per capita in the UK in 1890 was about \$4100 in 1990 international dollars. It grew 35
36 in the subsequent years by an average of 1.4% per year. Had it been growing at that same rate in the previous 36
37 300 years, income per capita in 1590 would have been \$61, which clearly seems absurdly low. 37

38 ⁴ Snooks (1994) belief in pre-modern growth is based essentially on his comparison between the income per 38
39 capita he has calculated from the Domesday book (1086) and the numbers provided by Gregory King for 1688. 39
40 While such computations are of course always somewhat worrisome (what, exactly, does it mean to estimate 40
41 the nominal income of 1086 in the prices of 1688 given the many changes in consumption items?), the order 41
42 of magnitude provided by Snooks (an increase of real income by 580 percent) may survive such concerns. 42
43 Maddison (2001, p. 265) estimates that GDP per capita in constant prices increased at a rate of 0.13 percent 43
44 in Western Europe between 1000 and 1500 and 0.15% between 1500 and 1820. In the UK and the Nether- 44
45 lands growth between 1500 and 1820 was about 0.28 percent per year. Medievalists tend to agree with the 45

1 parts of Asia were enjoying a standard of living that had not been experienced ever before, in terms of the quantity, quality, and variety of consumption.⁵ Pre-1750 growth was primarily based on Smithian and Northian effects: gains from trade and more efficient allocations due to institutional changes. The Industrial Revolution, then, can be regarded not as the beginnings of growth altogether but as the time at which technology began to assume an ever-increasing weight in the generation of growth and when economic growth accelerated dramatically. An average growth rate of 0.15–0.20% per annum, with high year-to-year variation and frequent setbacks was replaced by a much more steady growth rate of 1.5% per annum and better. Big differences in degree here are tantamount to differences in quality. This transition should not be confused with the demographic transition, which came later and whose relationship with technological progress is complex and poorly understood.⁶

13 This is not to say that before the Industrial Revolution technology was altogether unimportant in its impact on growth. Medieval Europe was an innovative society which invented many important things (including the mechanical clock, movable type, gunpowder, spectacles, iron-casting) and adopted many more inventions from other societies (paper, navigational instruments, Arabic numerals, the lateen sail, wind power). Yet, when all is said and done, it is hard to argue that the impact of these inventions on the growth of GDP or some other measure of aggregate output were all that large. The majority of the labor force was still employed in agriculture where progress was exceedingly slow (even if over the long centuries between 800 and 1300 the three-field system and the growing efficiency at which livestock was employed did produce considerable productivity gains).

24 Moreover, it is true for the pre-1750 era – as it was a fortiori after 1750 – that technology itself interacted with Smithian growth because on balance improved technology made the expansion of trade possible – above all maritime technology in all its many facets, but also better transport over land and rivers, better military technology to defeat

29 occurrence of economic growth in Britain, though their figures indicate a much slower rate of growth, about a 111 percent growth rate between 1086 and 1470 [Britnell (1996, p. 229)], which would require more economic growth in the sixteenth and seventeenth centuries than can be justified to square with Snooks' numbers. Engerman (1994, p. 116) assesses that most observers will agree with Snooks' view that by 1700 England had a high level of per capita income and was in a good position to "seek the next stage of economic growth". Yet clearly he is correct in judging that "modern" economic growth (prolonged, continuous, rapid) did not begin until the early nineteenth century.

35 ⁵ Indeed, many historians speak of a "consumer revolution" *prior to* the Industrial Revolution, which would be inexplicable without rising income before 1750. Lorna Weatherill (1988) suggests that if there was a Consumer Revolution at all, it peaked in the period 1680–1720. Moreover, consumer revolutions were taking place elsewhere in Europe. Seventeenth century Holland was, of course, the most obvious example thereof, but Cissie Fairchilds (1992) has employed probate records to show that France, like England, experienced a consumer revolution, albeit fifty years later.

41 ⁶ It is in that sense that the view of modern economists [e.g. Galor and Weil (2000, p. 809)] that "the key event that separates Malthusian and post-Malthusian regimes is the acceleration of the pace of technological progress" is a bit misleading, since it draws a link between technological progress and demographic change that thus far has not been closely examined.

1 pirates, better knowledge of remote lands, and the growing ability to communicate with 1
2 strangers. A decomposition of growth into a technology component and a trade-and 2
3 institutions component must take into account such interactions. 3

4 All the same, the main reason why technological progress was at best an also-ran 4
5 in the explanation of economic growth before 1750 is that even the best and bright- 5
6 est mechanics, farmers, and chemists – to pick three examples – knew relatively little 6
7 of what could be known about the fields of knowledge they sought to apply. The pre- 7
8 1750 world produced, and produced well. It made many pathbreaking inventions. But 8
9 it was a world of engineering without mechanics, iron-making without metallurgy, 9
10 farming without soil science, mining without geology, water-power without hydraulics, 10
11 dye-making without organic chemistry, and medical practice without microbiology and 11
12 immunology. Not enough was known to generate sustained economic growth based on 12
13 technological change.⁷ Such statements are of course to some extent provocative and 13
14 perhaps even irresponsible: how can we define “what could be known” in any mean- 14
15 ingful sense? Who knew “that which was known” and how did they use it? In what 15
16 follows I shall propose a simple framework to understand how and why new technology 16
17 emerges and how it was limited before the eighteenth century and then liberated from 17
18 its constraints. I will then argue that “technological modernity” means an economy in 18
19 which *sustained* technological progress is the primary engine of growth and that it de- 19
20 pended on the persistence of technological progress. What is needed is a good theory of 20
21 the kind of factors that make for sustained technological progress. 21

22 Such a theory needs to stress the basic complementarity between the creation and 22
23 diffusion of new technology and the institutional factors that allowed this knowledge 23
24 to be applied, become profitable, and lead to economic expansion. These institutional 24
25 factors – such as the establishment of intellectual property rights, the supply of venture 25
26 capital, the operation of well-functioning commodity and labor markets, and the pro- 26
27 tection of innovators and entrepreneurs against a technological reaction – are of central 27
28 importance but they have been discussed elsewhere [Mokyr (1998a, 2003b)] and in what 28
29 follows the focus will be on the growth of knowledge itself. All the same, it should be 29
30 kept in mind that growth cannot result from a growth of knowledge *alone*. It needs to 30
31 occur in an environment in which knowledge can be put to work. 31
32
33

34 3. A historical theory of technology 34 35 35

36 Technology is knowledge. Knowledge, as is well known, has always been a difficult 36
37 concept for standard economics to handle. It is at the core of modern economic growth, 37
38
39

40
41 ⁷ The great agronomist Arthur Young sighed hopefully in 1772 that while in his day the farmers were 41
42 largely ignorant of the “peculiar biasses” of individual soils, perhaps “one day the nature of all soils and 42
43 the vegetables they particularly affect will be known experimentally ... a desideratum in natural philosophy 43
44 worthy of another Bacon” [Young (1772, p. 168)].

1 but many characteristics make it slippery to handle. Knowledge is above all a non- 1
2 rivalrous good, that is, sharing it with another person does not diminish the knowledge 2
3 of the original owner. It is not quite non-excludable, but clearly excludability is costly 3
4 and for many types of knowledge exclusion costs are infinite. It is produced in the 4
5 system, but the motivation of its producers are rarely purely economic. Indeed, the pro- 5
6 ducers of scientific knowledge almost never collect but a tiny fraction of the surplus they 6
7 produce for society. It is the mother of all spillover effects. A more fruitful approach 7
8 than to view knowledge as an odd sort of good, pioneered by [Olsson \(2000, 2003\)](#), is 8
9 to model knowledge as a set, and to analyze its growth in terms of the properties of 9
10 existing knowledge rather than looking at the motivations of individual agents. 10

11 The basic unit of analysis of technology is the “technique”. A technique is a set of 11
12 instructions, much like a cookbook recipe, on how to produce goods and services. As 12
13 such, it is better defined than the concept of a stock of “ideas” that some scholars prefer 13
14 [e.g., [Charles Jones 2001](#)]. The entire set of feasible techniques that each society has at 14
15 its disposal is bound by the isoquant. Each point on or above the isoquant in principle 15
16 represents a set of instructions on how to combine various ingredients in some way 16
17 to produce a good or service that society wants. While technology often depends on 17
18 artifacts, the artifacts are not the same as the technique and what defines the technique 18
19 is the content of the instructions. Thus, a piano is an artifact, but what is done with 19
20 it depends on the technique used by the pianist, the tuner, or the movers. Society’s 20
21 production possibilities are bound by what society knows. This knowledge includes the 21
22 knowledge of designing and building artefacts and using them. 22

23 But who is “society”? The only sensible way of defining knowledge at a social level is 23
24 as the *union* of all the sets of individual knowledge. This definition is consistent with our 24
25 intuitive notion of the concept of an invention or a discovery – at first only *one* person 25
26 has it, but once that happens, society as a whole feels it has acquired it. Knowledge 26
27 can be stored in external storage devices such as books, drawings, and artifacts but 27
28 such knowledge is meaningless unless it can be transferred to an actual person. Such a 28
29 definition immediately requires a further elaboration: if one person possesses a certain 29
30 knowledge, how costly is it for others to acquire it? This question, indeed is at the heart 30
31 of the idea of a “technological society”. Knowledge is shared and distributed, and its 31
32 transmission through learning is essential for such a society to make effective use of it. 32
33 Between the two extremes of a society in which all knowledge acquired by one member 33
34 is “episodic” and not communicated to any other member, and the other extreme in 34
35 which all knowledge is shared instantaneously to all members through some monstrous 35
36 network, there was a reality of partial and costly sharing and access. But these costs were 36
37 not historically invariant, and the changes in them are one of the keys to technological 37
38 change. 38

39 Progress in exploiting the existing stock of knowledge will depend first and foremost 39
40 on the efficiency and cost of access to knowledge. Although knowledge is a public good 40
41 in the sense that the consumption of one does not reduce that of others, the private costs 41
42 of acquiring it are not negligible, in terms of time, effort, and often other real resources 42
43 as well [[Reiter \(1992, p. 3\)](#)]. Access costs include the costs of finding out whether an 43

1 answer to a question actually exists, if so, where it can be found, then paying the cost 1
2 of acquiring it, and finally verifying the correctness of the knowledge. When the ac- 2
3 cess costs become very high, it could be said in the limit that social knowledge has 3
4 disappeared.⁸ Language, mathematical symbols, diagrams, and physical models are all 4
5 means of reducing access costs. Shared symbols may not always correspond precisely 5
6 with the things they signify, as postmodern critics believe, but as long as they are shared 6
7 they reduce the costs of accessing knowledge held by another person or storage device. 7
8 The other component of access cost, tightness, is largely determined by the way soci- 8
9 ety deal with authority and trust. It is clear that propositional knowledge is always and 9
10 everywhere far larger than any single individual can know. The concepts of trust and 10
11 authority are therefore central to the role that propositional knowledge can play in soci- 11
12 ety, and how it is organized is central to the economic impact of useful knowledge. In 12
13 the scientific world of the late seventeenth and eighteenth centuries, a network of trust 13
14 and verification emerged in the West that seems to have stood the test of time. It is well 14
15 described by Polanyi (1962, pp. 216–222): the space of useful knowledge is divided in 15
16 small neighboring units. If an individual B is surrounded by neighbors A and C who 16
17 can verify his work, and C is similarly surrounded by B and D and so on, the world of 17
18 useful knowledge reaches an equilibrium in which science, as a whole, can be trusted 18
19 even by those who are not themselves part of it. 19

20 The determinants of these access costs are both institutional and technological: “open 20
21 knowledge” societies, in which new discoveries are published as soon as they are made 21
22 and in which new inventions are placed in the public domain through the patenting sys- 22
23 tem (even if their application may be legally restricted), are societies in which access 23
24 costs will be lower than in societies in which the knowledge is kept secret or con- 24
25 fined to a small and closed group of insiders whether they are priests, philosophers, or 25
26 mandarins. Economies that enjoyed a high level of commerce and mobility were sub- 26
27 ject to knowledge through the migration of skilled workmen and the opportunities to 27
28 imitate and reverse-engineer new techniques. As access costs fell in the early modern 28
29 period, it became more difficult to maintain intellectual property rights through high 29
30 access costs, and new institutions that provided incentives for innovators became neces- 30
31 sary, above all the patent system emerging in the late fifteenth and sixteenth centuries. 31
32 The printing press clearly was one of the most significant access-cost-reducing inven- 32
33 33

34 34
35 35
36 ⁸ This cost function determines how costly it is for an individual to access information from a storage device 36
37 or from another individual. The *average* access cost would be the average cost paid by all individuals who 37
38 wish to acquire the knowledge. More relevant for most useful questions is the *marginal* access cost, that is, 38
39 the *minimum* cost for an individual who does not yet have this information. A moment reflection will make 39
40 clear why this is so: it is very expensive for the average member of a society to have access to the Schrödinger 40
41 wave equations, yet it is “accessible” at low cost for advanced students of quantum mechanics. If someone 41
42 “needs” to know something, he or she will go to an expert for whom this cost is as low as possible to find 42
43 out. Much of the way knowledge has been used in recent times has relied on such experts. The cost of finding 42
44 them experts and retrieving knowledge thus determines marginal access costs. Equally important, as we shall 43
45 see, is the technology that provides access to storage devices. 43

1 tions of the historical past.⁹ The nature of the books printed, such as topic, language, 1
2 and accessibility, played an equally central role in their reduction. People normally ac- 2
3 quired knowledge and skills vertically, but also from one another through imitation. 3
4 Postdoctoral students in laboratory settings full-well realize the differences between 4
5 the acquisition of codifiable knowledge and the acquisition of tacit knowledge through 5
6 imitation and a certain *je ne sais quoi* we call experience.¹⁰ Improvements in trans- 6
7 port and communication technology, that made people more mobile and speeded up the 7
8 movement of mail and newspapers also reduced access costs in the second half of the 8
9 eighteenth century, a movement that continued through the nineteenth century and has 9
10 not stopped since. 10

11 Techniques constitute what I have called *prescriptive* knowledge – like any recipe 11
12 they essentially comprise instructions that allow people to “produce”, that is, to exploit 12
13 natural phenomena and regularities in order to improve human material welfare.¹¹ The 13
14 fundamental unit of set of prescriptive knowledge has the form of a set of do-loops 14
15 (often of great complexity, with many if–then statements), describing the “hows” of 15
16 what we call production. 16

17 There are two preliminary observations we need to point out in this context. One is 17
18 that it is impossible to specify explicitly the entire content of a set of instructions. Even 18
19 a simple cooking recipe contains a great deal of assumptions that the person executing 19
20 the technique is supposed to know: how much a cup is, when water is boiling, and so on. 20
21 For that reason, the person executing a technique is supposed to have certain knowledge 21
22 that I shall call *competence* to distinguish it from the knowledge involved in writing 22
23 the instructions for the first time (that is, actually making the invention). Competence 23
24 consists of the knowledge of how to read, interpret, and execute the instructions in the 24
25 technique and the supplemental tacit knowledge that cannot be fully written down in 25
26 the technique’s codified instructions. There is a continuum between the implicit under- 26
27 standings and clever tricks that make a technique work we call tacit knowledge, and 27
28 28

29
30 ⁹ Elizabeth Eisenstein (1979) has argued that the advent of printing created the background on which the 29
31 progress of science and technology rests. In her view, printing created a “bridge over the gap between town 30
32 and gown” as early as the sixteenth century, and while she concedes that “the effect of early printed technical 31
33 literature on science and technology is open to question” she still contends that print made it possible to 32
34 publicize “socially useful techniques” (pp. 558, 559). 33

34 ¹⁰ It should be obvious that in order to read such a set of instructions, readers need a “codebook” that ex- 34
35 plains the terms used in the technique [Cowan and Foray (1997)]. Even when the techniques are explicit, 35
36 the codebook may not be, and the codebook needed to decipher the first codebook and the next, and so on, 36
37 eventually must be tacit. Sometimes instructions are “tacit” even when they could be made explicit but it is 37
38 not cost-effective to do so. 38

38 ¹¹ These instructions are similar to the concept of “routines” proposed by Nelson and Winter (1982). When 38
39 these instructions are carried out in practice, we call it production, and then they are no longer knowledge but 39
40 action. “Production” here should be taken to include household activities such as cooking, cleaning, childcare, 40
41 and so forth, which equally require the manipulation of natural phenomena and regularities. It is comparable 41
42 to DNA instructions being “expressed”. Much like instructions in DNA, the lines in the technique can be 42
43 either “obligate” (do *X*) or “facultative” (if *Y*, do *X*). For more complex techniques, nested instructions are 43
44 the rule. 44

1 the minor improvements and refinements introduced subsequent to invention that in- 1
2 volve actual adjustments in the explicit instructions. The latter would be more properly 2
3 thought off as microinventions, but a sharp distinction between them would be arbitrary. 3
4 All the same, “competence” and “knowledge” are no less different than the differences 4
5 in skills needed to play the Hammerklavier sonata and those needed to compose it. One 5
6 of the most interesting variables to observe is the ratio between the knowledge that goes 6
7 into the first formulation of the technique in question (invention) and the competence 7
8 needed to actually carry out the technique. As we shall see, it is this ratio around which 8
9 the importance of human capital in economic growth will pivot. 9

10 The second observation is the notion that every technique, because it involves the 10
11 manipulation and harnessing of natural regularities, requires an *epistemic base*, that is, 11
12 a knowledge of nature on which it is based. I will call this type of knowledge *proposi-* 12
13 *tional* knowledge, since it contains a set of propositions about the physical world. The 13
14 distinction between propositional and prescriptive knowledge seems obvious: the planet 14
15 Neptune and the structure of DNA were not “invented”; they were already there prior to 15
16 discovery, whether we knew it or not. The same cannot be said about diesel engines or 16
17 aspartame. Polanyi (1962) notes that the distinction is recognized by patent law, which 17
18 permits the patenting of inventions (additions to prescriptive knowledge) but not of dis- 18
19 coveries (additions to propositional knowledge). He points out that the difference boils 19
20 down to observing that prescriptive knowledge can be “right or wrong” whereas “ac- 20
21 tion can only be successful or unsuccessful” (p. 175). Purists will object that “right” 21
22 and “wrong” are judgments based on socially constructed criteria, and that “success- 22
23 ful” needs to be defined in a context, depending on the objective function that is being 23
24 maximized. 24

25 The two sets of propositional and prescriptive knowledge together form the set of 25
26 useful knowledge in society. These sets satisfy the conditions set out by Olsson (2000) 26
27 for his “idea space”. Specifically, the sets are infinite, closed, and bounded. They also 27
28 are subsets of much larger sets, the sets of knowable knowledge. At each point of time, 28
29 the actual sets describe what a society knows and consequently what it can do. There 29
30 also is a more complex set of characteristics that connect the knowledge at time t with 30
31 that in the next period. Knowledge is mostly cumulative and evolutionary. The “mostly” 31
32 is added because it is not wholly cumulative (knowledge *can* be lost, though this has 32
33 become increasingly rare) and its evolutionary features are more complex than can be 33
34 dealt with here [Mokyr (2003a)]. 34

35 The actual relation between propositional and prescriptive knowledge can be sum- 35
36 marized in the following 10 generalizations: 36

- 37 1. Every technique has a minimum epistemic base, which contains the least knowl- 37
38 edge that society needs to possess for this technique to be invented. The epistemic 38
39 base contains at the very least the trivial statement that technique i works.¹² 39
40 40

41 41
42 ¹² This statement is true because the set of propositional knowledge contains as a subset the list (or catalog) 42
43 of the techniques that work – since that statement can be defined as a natural regularity. 43

- 1 There are and have been some techniques, invented accidentally or through trial 1
2 and error, about whose *modus operandi* next to nothing was known except that 2
3 they worked. We can call these techniques *singleton* techniques (since their do- 3
4 main is a singleton). 4
- 5 2. Some techniques require a minimum epistemic base larger than a singleton for 5
6 a working technique to emerge. It is hard to imagine the emergence of such 6
7 techniques as nuclear resonance imaging or computer assisted design software 7
8 in any society from serendipitous finds or trial-and-error methods, without the 8
9 designers having a clue of why and how they worked. 9
- 10 3. The actual epistemic base is equal to or larger than the minimum epistemic base. 10
11 It is never bound from above in the sense that the amount that can be known about 11
12 the natural phenomena that govern a technique is infinite. In a certain sense, we 12
13 can view the epistemic base at any given time much like a fixed factor in a pro- 13
14 duction function. As long as it does not change, it imposes concavity and possibly 14
15 even an upper bound on innovation and improvement. On the other hand, beyond 15
16 a certain point, the incremental effect of widening the actual epistemic base on 16
17 the productivity growth of a given technique will run into diminishing returns 17
18 and eventually be limited. 18
- 19 4. There is no requirement that the epistemic base be “true” or “correct” in any 19
20 sense. In any event, the only significance of such a statement would be that it 20
21 conforms to contemporary beliefs about nature (which may well be refuted by 21
22 future generations). Thus the humoral theory of disease, now generally rejected, 22
23 formed the epistemic base of medical techniques for many centuries. At the same 23
24 time, some epistemic bases can be more effective than others in the sense that 24
25 techniques based on them perform “better” by some agree-upon criterion. “Ef- 25
26 fective knowledge” does not mean “true knowledge” – many techniques were 26
27 based on knowledge we no longer accept yet were deployed for long periods 27
28 with considerable success.¹³ 28
- 29 5. The wider the actual epistemic base supporting a technique relative to the min- 29
30 imum one, the more likely an invention is to occur, *ceteris paribus*. A wider 30
31 epistemic base means that it is less likely for a researcher to enter a blind alley 31
32 and to spend resources in trying to create something that cannot work.¹⁴ Thus, 32
33 a wider epistemic base reduces the costs of research and development and in- 33
34 creases the likelihood of success. 34

35
36
37 ¹³ Here one can cite many examples. Two of them are the eighteenth century metallurgical writings and 36
38 inventions of René Réaumur and Tobern Bergman, firmly based on phlogiston physics, and the draining of 37
39 swamps based on the belief that the “bad air” they produced caused malaria. 38

39 ¹⁴ Alchemy – the attempt to turn base metals into gold by chemical means – was still a major occupation of 39
40 the best minds of the scientific revolution above all Isaac Newton. By 1780 Alchemy was in sharp decline 40
41 and in the nineteenth century chemists knew enough to realize that it was a misallocation of human capital to 41
42 search for the stone of the wise or the fountain of youth. The survival of astrology in our time demonstrates 42
43 that the prediction of the future – always a technique based on a very narrow epistemic base – has not benefited 43
44 in a similar way from a widening of the prescriptive knowledge on which it was based. 43

- 1 6. The wider the epistemic base, the more likely an existing technique is to be im- 1
2 proved, adapted, and refined through subsequent microinventions. The more is 2
3 known about the principles of a technique, the lower will be the costs of de- 3
4 velopment and improvement. This is above all because the more is known *why* 4
5 something works, the better the inventor can tweak its parameters to optimize and 5
6 debug the technique. Furthermore, because invention so often consists of analogy 6
7 with or the recombination of existing techniques, lower access cost to the catalog 7
8 of existing techniques (which is part of propositional knowledge) stimulates and 8
9 streamlines successful invention. 9
- 10 7. Historically, the epistemic bases in existence during the early stages of an inven- 10
11 tion are usually quite narrow at first, but in the last two centuries have often been 11
12 enlarged following the appearance of the invention, and sometimes directly on 12
13 account of the invention. 13
- 14 8. Both propositional and prescriptive knowledge can be “tight” or “untight”. Tight- 14
15 ness measures the degree of confidence and consensualness of a piece of knowl- 15
16 edge: how sure are people that the knowledge is “true” or that the technique 16
17 “works”? The tighter a piece of propositional knowledge, the lower are the costs 17
18 of verification and the more likely a technique based on it is to be adopted, and 18
19 vice versa. Of course, tightness is correlated with effectiveness: a laser printer 19
20 works better than a dot matrix, and there can be little dispute about the charac- 20
21 teristics here. If two techniques are based on incompatible epistemic bases, the 21
22 one that works better will be chosen and the knowledge on which it is based will 22
23 be judged to be more effective. But for much of history, such testing turned out 23
24 to be difficult to do and propositional knowledge was more often selected on the 24
25 basis of authority and tradition than effectiveness. Even today, for many medical 25
26 and farming techniques it is often difficult to observe what works and what does 26
27 not work as well without careful statistical analysis or experimentation. 27
- 28 9. It is not essential that the person writing the instructions actually knows himself 28
29 everything that is in the epistemic base. Even if very few individuals in a society 29
30 know quantum mechanics, the practical fruits of the insights of this knowledge 30
31 to technology may still be available just as if everyone had been taught advanced 31
32 physics. It is a fortiori true that the people carrying out a set of instructions do 32
33 not know how and why these instructions work, and what the support for them 33
34 is in propositional knowledge. No doctor prescribing nor any patient taking an 34
35 aspirin will need to study the biochemical properties of prostaglandins, though 35
36 such knowledge may be essential for those scientists working on a design of 36
37 an analgesic with, say, fewer side effects. What counts is collective knowledge 37
38 and the cost of access as discussed above. It is even less necessary for the people 38
39 actually carrying out the technique to possess the knowledge on which it is based, 39
40 and normally this is not the case. 40
- 41 10. The existence of a minimum epistemic base is a necessary but insufficient con- 41
42 dition for a technique to emerge. A society may well accumulate a great deal 42
43 of propositional knowledge that is never translated into new and improved tech- 43

1 niques. Knowledge opens doors, but it does not force society to walk through 1
2 them. 2
3 3
4 4

5 **4. The significance of the Industrial Revolution** 5 6 6

7 Historians in the 1990s have tended to belittle the significance of the Industrial Revo- 7
8 lution as a historical phenomenon, referring to it as the so-called Industrial Revolution, 8
9 and pointing to the slowness and gradualness of economic change, as well as the many 9
10 continuities that post 1760 Britain had with earlier times [for a critical survey, see Mokyr 10
11 (1998b)]. 11
12 12

13 Before I get to the heart of the argument, two points need to be cleared away. The 13
14 first is the myth that the Industrial Revolution was a purely British affair, and that with- 14
15 out Britain's leadership Europe today would still be largely a subsistence economy. The 15
16 historical reality was that many if not most of the technological elements of the Indus- 16
17 trial Revolution were the result of a joint international effort in which French, German, 17
18 Scandinavian, Italian, American and other "western" innovators collaborated, swapped 18
19 knowledge, corresponded, met one another, and read each others' work. 19

20 It is of course commonplace that in most cases the first successful economic *appli-* 20
21 *cations* of the new technology appeared in Britain. By 1790 Britain had acquired an 21
22 advantage in the execution of new techniques. Yet an overwhelming British advantage 22
23 in *inventing* – especially in generating the crucial macroinventions that opened the doors 23
24 to a sustained trajectory of continuing technological change – is much more doubtful, 24
25 and their advantage in expanding the propositional knowledge that was eventually to 25
26 widen the epistemic bases of the new techniques is even more questionable. Britain's 26
27 technological precociousness in the era of the Industrial Revolution was a function of 27
28 three factors. 28

29 First, by the middle of the eighteenth century Britain had developed an institutional 29
30 strength and agility that provided it with a considerable if temporary advantage over 30
31 its Continental competitors: it had a healthier public finance system, weaker guilds, no 31
32 internal tariff barriers, a superior internal transportation system, fairly well-defined and 32
33 enforceable property rights on land (enhanced and modified by Parliamentary acts when 33
34 necessary), and a power structure that favored the rich and the propertied classes. More- 34
35 over, it had that most elusive yet decisive institutional feature that makes for economic 35
36 success: the flexibility to adapt its economic and legal institutions without political 36
37 violence and disruptions. Britain's great asset was not so much that she had "better" 37
38 government but rather that its political institutions were nimbler, and that they could be 38
39 changed at low social cost by a body assigned to changing the rules and laws by which 39
40 the economic game was played. Many of the rules still on the books in the eighteenth 40
41 century were not enforced, and rent seeking arrangements, by comparison, were costly 41
42 to attain and uncertain in their yield. British mercantilist policy was already in decline 42
43 on the eve of the Industrial Revolution. Yet as the Industrial Revolution unfolded, it 43

1 required further change in the institutional basis of business. The Hanoverian govern- 1
2 ments in Britain were venal and nepotist, and much of the business of government was 2
3 intended to enrich politicians. On the Continent matters were no better. But with the 3
4 growing notion that rent seeking was harmful, this kind of corruption weakened [Mokyr 4
5 (2003b)]. As Porter (1990, p. 119) put it, with the rise of the laissez faire lobby, West- 5
6 minster abandoned its long-standing mercantilist paternalism, repealing one regulation 6
7 after another. Abuses may have been deep rooted, and entrenched rent-seekers resisted 7
8 all they could, but from the last third of the eighteenth century on rent-seeking was on 8
9 the defensive, and by 1835 many of the old institutions had vanished, and the British 9
10 state, for a few decades, gave up on redistributing income as a main policy objective. 10
11 Following North (1990, p. 80) we might call this adaptive efficiency, meaning not only 11
12 the adaptation of the allocation of resources but of the institutions themselves. To bring 12
13 this about, what was needed was a meta-institution with a high degree of legitimacy, 13
14 such as parliament, that was authorized to change the rules in a consensual manner. 14

15 Second, Britain's entrepreneurs proved uncannily willing and able to adopt new in- 15
16 ventions regardless of where they were made, free from the "not made here" mentality 16
17 of other societies. Some of the most remarkable inventions made on the Continent were 17
18 first applied on a wide scale in Britain. Among those, the most remarkable were gas- 18
19 lighting, chlorine bleaching, the Jacquard loom, the Robert continuous paper-making 19
20 machine, and the Leblanc soda making process. In smaller industries, too, the debt of the 20
21 British Industrial Revolution to Continental technology demonstrates that in no sense 21
22 did Britain monopolize the inventive process.¹⁵ The British advantage in application 22
23 must be chalked up largely to its comparative advantage in microinventions and in the 23
24 supply of the human capital that could carry out the new techniques.¹⁶ To employ the 24
25

26
27 ¹⁵ The great breakthrough in plate glass was made in France by a Company founded in the 1680s, which cast 27
28 a far superior product by pouring it over a perfectly smooth metallic table, a concept as simple in principle 28
29 as it was hard to carry out in practice but perfected by the St. Gobain company. The British tried for many 29
30 decades to copy the process, but never matched the French for quality Harris (1992b, p. 38). The most impor- 30
31 tant subsequent breakthrough in the glass industry was made in 1798 by Pierre Louis Guinand, a Swiss, who 31
32 invented the stirring process in which he stirred the molten glass in the crucible using a hollow cylinder of 32
33 burnt fireclay, dispersing the air bubbles in the glass more evenly. The technique produced optical glass of un- 33
34 precedented quality. Guinand kept his process secret, but his son sold the technique to a French manufacturer 34
35 in 1827, who in turn sold it to the Chance Brothers Glass Company in Birmingham, which soon became one 35
36 of the premier glassmakers in Europe. The idea of preserving food by cooking followed by vacuum sealing 36
37 was hit upon by the Frenchman Nicolas Appert in 1795. Appert originally used glassware to store preserved 37
38 foods, but in 1812 an Englishman named Peter Durand suggested using tin-plated cans, which were soon 38
39 found to be superior. By 1814, Bryan Donkin was supplying canned soups and meats to the Royal Navy. 39

40 ¹⁶ This was already pointed by Daniel Defoe, who pointed out in 1726 that "the English . . . are justly fam'd 40
41 for improving Arts rather than inventing" and elsewhere in his Plan of English Commerce that "our great 41
42 Advances in Arts, in Trade, in Government and in almost all the great Things we are now Masters of and in 42
43 which we so much exceed all our Neighbouring Nations, are really founded upon the inventions of others". 43
44 The great engineer John Farey, who wrote an important treatise on steam power, testified a century later that 44
45 "the prevailing talent of English and Scotch people is to apply new ideas to use, and to bring such applications 45
46 to perfection, but they do not imagine as much as foreigners". 46

1 terminology proposed earlier: Britain may not have had more propositional knowledge 1
2 available for its invention and innovation process, but if its workers possessed higher lev- 2
3 els of competence, then the new techniques that emerged were more likely to find their 3
4 first applications there. Its successful system of informal technical training, through 4
5 master-apprentice relationships, created workers of uncommon skill and mechanical 5
6 ability [Humphries (2003)]. Britain also was lucky to have a number of successful in- 6
7 dustries that generated significant technical spillovers to other industries.¹⁷ This system 7
8 produced, of course, inventors: the most famous of these such as the clockmakers John 8
9 Harrison and Benjamin Huntsman, the engineer John Smeaton, the instrument maker 9
10 Jesse Ramsden, the wondrously versatile inventor Richard Roberts, the chemists James 10
11 Keir and Joseph Black, and of course Watt himself were only the first row of a veritable 11
12 army of people, who in addition to possessing formal knowledge, were blessed by a 12
13 technical intuition and dexterity we identify as the very essence of tacit knowledge. 13

14 Third, Britain was at peace in a period when the Continent was engulfed in political 14
15 and military upheaval. Not only that there was no fighting and political chaos on British 15
16 soil; the French revolution and the Napoleonic era was a massive distraction of talent 16
17 and initiative that would otherwise have been available to technology and industry.¹⁸ 17
18 The attention of both decision makers and inventors was directed elsewhere.¹⁹ During 18
19 the stormy years of the Revolution, French machine breakers found an opportunity to 19
20 mount an effective campaign against British machines, thus delaying their adoption 20
21 [Horn (2003)]. 21

22 Compared to Britain, the Continental countries had to make a greater effort to cleanse 22
23 their economic institutions from medieval debris and the fiscal ravages of absolutism, 23
24 24

25 25
26 ¹⁷ A number of high-skill sectors that had developed in Britain since 1650 played important roles in later 26
27 technological development. Among those instrument- and clock-making, mining, and ship yards were of 27
28 central importance. Cardwell (1972, p. 74) points out that a number of basic technologies converge on mining 28
29 (chemistry, civil engineering, metallurgy) and that mining sets the hard, “man-sized” problems, controlling 29
30 powerful forces of nature and transforming materials on a large scale. In addition, however, British millwrights 30
31 were technologically sophisticated: the engineer John Fairbairn, a millwright himself, noted that eighteenth 31
32 century British millwrights were “men of superior attainments and intellectual power”, and that the typical 32
33 millwright would have been “a fair arithmetician, knew something of geometry, levelling and mensuration 33
34 and possessed a very competent knowledge of practical mechanics” [cited in Musson and Robinson (1969, 34
35 p. 73)]. 35

36 ¹⁸ The chemists Claude Berthollet and Jean-Antoine Chaptal, for instance, both directed their abilities to 36
37 administration during the Empire. Their illustrious teacher, the great Lavoisier himself, was executed as a tax 37
38 farmer. Another example is Nicolas de Barneville, who was active in introducing British spinning equipment 38
39 into France. De Barneville repeatedly was called upon to serve in military positions and was “one of those 39
40 unfortunate individuals whose lives have been marred by war and revolution . . . clearly a victim of the troubled 40
41 times” [McCloy (1952, pp. 92–94)]. 41

42 ¹⁹ The Frenchman Philippe LeBon, co-inventor of gas-lighting in the 1790s, lost out in his race for priority 42
43 with William Murdoch, the ingenious Boulton and Watt engineer whose work in the end led the introduction 43
44 of this revolutionary technique in the illumination of the Soho works in 1802. As one French historian sighs, 44
45 “during the terrors of the Revolution . . . no one thought of street lights. When the mob dreamed of lanterns, it 45
46 was with a rather different object in view” [cited by Griffiths (1992, p. 242)]. 46

1 undo a more complex and pervasive system of rent seeking and regulation, and while 1
2 extensive reforms were carried out in France, Germany, and the Low Countries after 2
3 the French Revolution, by 1815 the work was still far from complete and had already 3
4 incurred enormous social costs. It took another full generation for the Continent to pull 4
5 even. All the same, none of the British advantages was particularly deep or permanent. 5
6 They explain Britain's position as the lead car in the Occident Express that gathered 6
7 steam in the nineteenth century and drove away from the rest of the world, but it does 7
8 not tell us much about the source of power. Was Britain the engine that pulled the other 8
9 European cars behind it, or was Western Europe like an electric train deriving its motive 9
10 power from a shared source of energy? 10

11 One useful mental experiment is to ask whether there would have been an Industrial 11
12 Revolution in the absence of Britain. A counterfactual industrial revolution led by Con- 12
13 tinental economies would have been delayed by a few decades and differed in some 13
14 important details. It might have relied less on "British" steam and more on "French" 14
15 water power and "Dutch" wind power technology, less on cotton and more on wool and 15
16 linen. It would probably have had more of an *étatist* and less of a free-market flavor, 16
17 with a bigger emphasis on military engineering and public projects. Civil servants and 17
18 government engineers might have made some decisions that were made by entrepre- 18
19 neurs. But in view of the capabilities of French engineers and German chemists, the 19
20 entrepreneurial instincts of Swiss and Belgian industrialists, and the removal of many 20
21 institutions that had hampered the effective deployment of talents and resources on the 21
22 Continent before 1789, a technological revolution would have happened not all that 22
23 different from what actually transpired. Even without Britain, by the twentieth century 23
24 the 1914 gap between Europe and the rest of the world would have been there [Mokyr 24
25 (2000)]. 25

26 The second point to note is that the pivotal element of the Industrial Revolution took 26
27 place later than is usually thought. The difference between the Industrial Revolution of 27
28 the eighteenth century and other episodes of a clustering of macroinventions was not just 28
29 in the celebrated inventions in the period 1765–1790. While the impact of the technologi- 29
30 cal breakthroughs of these years of *sturm und drang* on a number of critical industries 30
31 stands undiminished, the critical difference between this Industrial Revolution and pre- 31
32 vious clusters of macroinventions is not that these breakthroughs occurred at all, but 32
33 that their momentum did not level off and peter out after 1800 or so. In other words, 33
34 what made the Industrial Revolution into the "great divergence" was the *persistence* 34
35 of technological change after the first wave. We might well imagine a counterfactual tech- 35
36 nological steady state of throstles, wrought iron, and stationary steam engines, in which 36
37 there was a one-off shift from wool to cotton, from animate power to stationary engines, 37
38 and from expensive to plentiful wrought iron. It is easy to envisage the economies of the 38
39 West settling into these techniques without taking them much further, as had happened 39
40 in the wave of inventions of the fifteenth century. 40

41 But this is not what happened. The "first wave" of innovations was followed after 41
42 1820 by a secondary ripple of inventions that may have been less spectacular, but these 42
43 were the microinventions that provided the muscle to the downward trend in produc- 43

1 tion costs. The second stage of the Industrial Revolution adapted ideas and techniques 1
2 to be applied in new and more industries, improved and refined earlier inventions, ex- 2
3 tended and deepened their deployment, and eventually these efforts showed up in the 3
4 productivity statistics. Among the remarkable later advances we may list the perfec- 4
5 tion of mechanical weaving after 1820; the invention of Roberts' self-acting mule in 5
6 spinning (1825); the extension and adaptation of the techniques first used in cotton 6
7 and worsted to carded wool and linen; the improvement in the iron industry through 7
8 Neilson's hot blast (1829) and related inventions; the continuous improvement in cru- 8
9 cible steelmaking through coordinated crucibles (as practiced for example by Krupp in 9
10 Essen); the pre-Bessemer improvements in steel thanks to the work of Scottish steel- 10
11 makers such as David Mushet (father of Robert Mushet, celebrated in one of Samuel 11
12 Smiles's *Industrial Biographies*), and the addition of manganese to crucible steel known 12
13 as Heath's process (1839); the continuing improvement in steampower, raising the ef- 13
14 ficiency and capabilities of the low pressure stationary engines, while perfecting the 14
15 high pressure engines of Trevithick, Woolf and Stephenson and adapting them to trans- 15
16 portation; the advances in chemicals before the advent of organic chemistry (such as the 16
17 breakthroughs in candle-making and soap manufacturing thanks to the work of Eugène- 17
18 Michel Chevreul on fatty acids); the introduction and perfection of gas-lighting; the 18
19 breakthroughs in high-precision engineering and the development of better machine- 19
20 tools by Maudslay, Whitworth, Nasmyth, Rennie, the Brunels, the Stephensons, and 20
21 the other great engineers of the "second generation"; the growing interest in electrical 21
22 phenomena leading to electroplating and the work by Hans Oersted and Joseph Henry 22
23 establishing the connection between electricity and magnetism, leading to the telegraph 23
24 in the late 1830s. 24

25 The second wave of inventions was the critical period in the sense that it shows up 25
26 clearly in the total income statistics. Income per capita growth after 1830 accelerates 26
27 to around 1.1 percent, even though recent calculations confirm that only about a third 27
28 of that growth to total factor productivity growth [Antrás and Voth (2003, p. 63) and 28
29 Mokyr (2003c)]. Income growth in Britain during the "classical" Industrial Revolution 29
30 was modest. This fact is less difficult to explain than some scholars make it out to 30
31 be, and any dismissal of the Industrial Revolution as a historical watershed for that 31
32 reason seems unwarranted. After all, the disruptions of international commerce during 32
33 the quarter century of the French Wars coincided with bad harvests and unprecedented 33
34 population growth. Yet the main reason is simply that in the early decades the segment 34
35 of the British economy affected by technological progress and that can be regarded as 35
36 a "modern sector" was simply small, even if its exact dimensions remain in dispute. 36
37 After 1830 this sector expands rapidly as the new technology is applied more broadly 37
38 (especially to transportation), growth accelerates, and by the mid-1840s there is clear- 38
39 cut evidence that the standard of living in Britain is rising even for the working class. 39
40 It also serves as a bridge between the first Industrial Revolution and the more intense and 40
41 equally dramatic changes of the second Industrial Revolution. 41

42 The success of the Industrial Revolution in generating sustainable economic growth, 42
43 then, must be found in the developments in the area of useful knowledge that occurred in 43

1 Europe before and around 1750. What mattered was not so much scientific knowledge 1
2 itself but the method and culture involving the generation and diffusion of proposi- 2
3 tional knowledge. The Industrial Revolution and its aftermath were based on a set of 3
4 propositional knowledge that was not only increasing in size, but which was becoming 4
5 increasingly accessible, and in which segments that were more effective were becom- 5
6 ing tighter. The effectiveness of propositional knowledge was increasingly tested by 6
7 whether the techniques that were based on it actually worked satisfactorily either by 7
8 experiment or by virtue of economic efficiency. 8

9 To sum up, then, the period 1760–1830 Western Europe witnessed a growing im- 9
10 portance of improving technology in economic growth. The emergence and continuous 10
11 improvement of new techniques that in the longer run were to have an enormous impact 11
12 on productivity and growth. People started to know more about how and why the tech- 12
13 niques they used worked, and this knowledge was widespread. Without belittling the 13
14 other elements that made the Industrial Revolution possible, the technological break- 14
15 throughs of the period prepared the ground for the economic transformation that made 15
16 the difference between the West and the Rest, between technological modernity and 16
17 the much slower and often-reversed economic growth episodes of the previous millennia. In 17
18 order to come up with a reasonable explanation of the technological roots of economic 18
19 growth in this period, we must turn to the intellectual foundations of the explosion of 19
20 technical knowledge. 20
21

22 23 24 **5. The intellectual roots of the Industrial Revolution**

25
26 Economic historians like to explain economic phenomena with other economic phe- 26
27 nomena. The Industrial Revolution, it was felt for many decades should be explained 27
28 by economic factors. Relative prices, better property rights, endowments, changes in 28
29 fiscal and monetary institutions, investment, savings, exports, and changes in labor sup- 29
30 ply have all been put forward as possible explanations [for a full survey, see [Mokyr](#) 30
31 [\(1998a\)](#)]. Yet the essence of the Industrial Revolution was technological, and technol- 31
32 ogy is knowledge. How, then, should we explain not just the famous inventions of the 32
33 Industrial Revolution but also the equally portentous fact that these inventions did not 33
34 peter out fairly quickly after they emerged, as had happened so often in the past? 34

35 The answer has to be sought in the intellectual changes that occurred in Europe *before* 35
36 the Industrial Revolution. These changes affected the sphere of propositional knowl- 36
37 edge, and its interaction with the world of technology. As economic historians have 37
38 known for many years, it is very difficult to argue that the scientific revolution of the 38
39 seventeenth century we associate with Galileo, Descartes, Newton, and the like had a 39
40 direct impact on the Industrial Revolution [[McKendrick \(1973\)](#) and [Hall \(1974\)](#)]. Few 40
41 important inventions, both before and after 1800, can be directly attributed to great 41
42 scientific discoveries or were dependent in any direct way on scientific expertise. The 42
43 advances in physics, chemistry, biology, medicine, and other areas occurred too late to 43

1 have an effect on the industrial changes of the last third of the eighteenth century.²⁰ The 1
2 scientific advances of the seventeenth century, crucial as they were to the understanding 2
3 of nature, had more to do with the movement of heavenly bodies, optics, magnetism, 3
4 and the classification of plants than with the motions of machines. To say that there- 4
5 fore they had no economic significance is an exaggeration: many of the great scientists 5
6 and mathematicians of the eighteenth century wrote about mechanics and the properties 6
7 of materials. After 1800 the connection becomes gradually tighter, yet the influence of 7
8 science proper on some branches of production (and by no means all at that) does not 8
9 become decisive until after 1870.²¹ The marginal product of scientific knowledge proper 9
10 on technology varied from industry to industry and over time. Examples of useful ap- 10
11 plications of pure scientific insights in the eighteenth century can be provided [Musson 11
12 and Robinson (1969)], but they tend to be specific to a few industries.²² 12

13 All the same, the scientific revolution was in many ways the prelude to the intellec- 13
14 tual developments at the base of the Industrial Revolution. The culture of science that 14
15 evolved in the seventeenth century meant that observation and experience were placed 15
16 in the public domain. Betty Jo Dobbs (1990), William Eamon (1990, 1994), and more 16
17 recently Paul David (2004) have pointed to the scientific revolution of the seventeenth 17
18 century as the period in which “open science” emerged, when knowledge about the nat- 18
19 ural world became increasingly nonproprietary and scientific advances and discoveries 19
20 were freely shared with the public at large. Thus scientific knowledge became a pub- 20
21 lic good, communicated freely rather than confined to a secretive exclusive few as had 21
22 been the custom in medieval Europe. The sharing of knowledge within “open science” 22
23 required systematic reporting of methods and materials using a common vocabulary and 23
24 consensus standards, and should be regarded as an exogenous decline in access costs, 24
25 which made the propositional knowledge, such as it was, available to those who might 25
26 find a use for it. Those who added to useful knowledge would be rewarded by honor, 26
27 peer recognition, and fame – not a monetary reward that was in any fashion propor- 27
28 tional to their contribution. Even those who discovered matters of significant insight to 28
29

30
31 ²⁰ Unlike the technologies that developed in Europe and the United States in the second half of the nineteenth 30
32 century, science, in this view, had little direct guidance to offer to the Industrial Revolution [Hall (1974, 31
33 p. 151)]. Shapin (1996) notes that “it appears unlikely that the ‘high theory’ of the Scientific Revolution had 32
34 any substantial direct effect on economically useful technology either in the seventeenth century or in the 33
35 eighteenth . . . historians have had great difficulty in establishing that any of these spheres of technologically 34
36 or economically inspired science bore substantial fruits” (pp. 140–141, emphasis added). 35

36
37 ²¹ As Charles Gillispie has remarked in the eighteenth century, whatever the interplay between science and 36
38 production may have been, “it did *not* consist in the application of up-to-date theory to techniques for growing 37
39 and making things” [Gillispie (1980, p. 336)]. True enough, but had progress only consisted of analyzing 38
40 existing procedures, identify the best of them, try to make them work as well as possible, and then standardize 39
41 them, the process would eventually have run into diminishing returns and fizzled out. 40

41
42 ²² Thus the most spectacular insight in metallurgical knowledge, the celebrated 1786 paper by Monge, 41
43 Berthollet and Vandermonde that established the chemical properties of steel had no immediate technological 42
44 spin-offs and was “incomprehensible except to those who already knew how to make steel” [Harris (1992a, 43
45 p. 220)]. Harris adds that there may have been real penalties for French steelmaking in its heavy reliance on 44
46 scientists or technologists with scientific pretensions. 45

1 industry, such as Claude Berthollet, Joseph Priestley and Humphry Davy, often wanted 1
2 credit, not profit. 2

3 The rhetorical conventions in scientific discourse changed in the seventeenth cen- 3
4 tury, with the rules of persuasions continuously shifting away from “authority” toward 4
5 empirics. It increasingly demanded that empirical knowledge be tested so that useful 5
6 knowledge could be both accessible and trusted.²³ Verification meant that a deliberate 6
7 effort was made to make useful knowledge tighter and thus more likely to be used. It 7
8 meant a willingness, rarely observed before, to discard old and venerable interpretations 8
9 and theories when they could be shown to be in conflict with the evidence. Scientific 9
10 method meant that in the age of enlightenment a class of experts evolved who often 10
11 would decide which technique worked best.²⁴ 11

12 The other crucial transformation that the Industrial Revolution inherited from the 12
13 seventeenth century was the growing change in the very purpose and objective of propo- 13
14 sitional knowledge. Rather than proving some religious point, such as illustrating the 14
15 wisdom of the creator, or the satisfaction of that most creative of human characteristics, 15
16 curiosity, natural philosophers in the eighteenth century increasingly came under the 16
17 influence of the idea that the main purpose of knowledge was to improve mankind’s ma- 17
18 terial condition – that is, find technological applications. Bacon in 1620 had famously 18
19 defined technology by declaring that the control of humans over things depended on 19
20 the accumulated knowledge about how nature works, since “she was only to be com- 20
21 manded by obeying her”. This idea was of course not entirely new, and traces of it can 21
22 be found in medieval thought and even in Plato’s *Timaeus*, which proposed a rationalist 22
23 view of the Universe and was widely read by twelfth-century intellectuals. In the seven- 23
24 teenth century, however, the practice of science became increasingly permeated by the 24
25 Baconian motive of material progress and constant improvement, attained by the accu- 25
26 mulation of knowledge.²⁵ The founding members of the Royal Society justified their 26
27 activities by their putative usefulness to the realm. There was a self-serving element 27
28

29
30 ²³ Shapin (1994) has outlined the changes in trust and expertise in Britain during the seventeenth century 29
31 associating expertise, for better or for worse, with social class and locality. While the approach to science 30
32 was ostensibly based on a “question authority” principle (the Royal Society’s motto was *nullius in verba* – on 31
33 no one’s word), in fact no system of useful (or any kind of) knowledge can exist without some mechanism 32
34 that generates trust. The apparent skepticism with which scientists treated the knowledge created by their 33
35 colleagues increased the trust that outsiders could have in the findings, because they could then assume – as 34
36 is still true today – that these findings had been scrutinized and checked by other “experts”. 35

36 ²⁴ As Hilaire-Pérez (2000 p. 60) put it, “the value of inventions was too important an economic stake to be 36
37 left to be dissipated among the many forms of recognition and amateurs: the establishment of truth became 37
38 the professional responsibility of academic science”. 38

39 ²⁵ Robert K. Merton (1970 [1938], pp. ix, 87) asked rhetorically how “a cultural emphasis upon social utility 39
40 as a prime, let alone an exclusive criterion for scientific work affects the rate and direction of advance in 40
41 science” and noted that “science was to be fostered and nurtured as leading to the improvement of man’s lot 41
42 by facilitating technological invention”. He might have added that non-epistemic goals for useful knowledge 42
43 and science, that is to say, goals that transcend knowledge for its own sake and look for some application, 43
44 affected not only the rate of growth of the knowledge set but even more the chances that existing knowledge 44
45 will be translated into techniques that actually increase economic capabilities and welfare. 45

1 in this, of course, much as with National Science Foundation grant proposals today. 1
2 Practical objectives in the seventeenth century were rarely the primary objective of the 2
3 growth of formal science. But the changing cultural beliefs implied a gradual change in 3
4 the agenda of research. 4

5 And yet, the central intellectual change in Europe before the Industrial Revolution 5
6 has been oddly neglected by economic historians: the Enlightenment. Historically it 6
7 bridges between the Scientific and the Industrial Revolutions. Definitions of this amor- 7
8 phous and often contradictory historical phenomenon are many, but for the purposes 8
9 of explaining the Industrial Revolution we only to examine a slice of it, which I have 9
10 termed the *Industrial Enlightenment*. To be sure, some historians have noted the im- 10
11 portance of the Enlightenment as a culture of rationality, progress, and growth through 11
12 knowledge.²⁶ Perhaps the most widely diffused Enlightenment view involved the no- 12
13 tion that long-term social improvement was possible although not all Enlightenment 13
14 philosophers believed that progress was either desirable or inevitable. Above all was 14
15 the pervasive cultural belief in the Baconian notion that we can attain material progress 15
16 (that is, economic growth) through controlling nature and that we can only harness na- 16
17 ture by understanding her. Francis Bacon, indeed, is a pivotal figure in understanding 17
18 the Industrial Enlightenment and its impact. His influence helped create the attitudes, 18
19 the institutions, and the mechanisms by which new useful knowledge was generated, 19
20 spread, and put to good use. Modern scholars seem agreed: Bacon was the first to regard 20
21 knowledge as subject to constant growth, an entity that continuously expands and adds 21
22 to itself rather than concerned with retrieving, preserving and interpreting old knowl- 22
23 edge [Farrington (1979) and Vickers (1992, esp. pp. 496–497)].²⁷ The understanding 23
24 of nature was a social project in which the division of knowledge was similar to Adam 24
25 Smith’s idea of the division of labor, another enlightenment notion.²⁸ Bacon’s idea of 25
26 bringing this about was through what he called a “House of Salomon” – a research 26
27 academy in which teams of specialists collect data and experiment, and a higher level 27
28 of scientists try to distill these into general regularities and laws. Such an institution 28

29
30
31 ²⁶ One of the most cogent statements is in McNeil (1987, pp. 24–25) who notes the importance of a “faith 30
31 in science that brought the legacy of the Scientific Revolution to bear on industrial society . . . it is impera- 31
32 tive to look at the interaction between culture *and* industry, between the Enlightenment and the Industrial 32
33 Revolution”. 33

34 ²⁷ Bacon was pivotal in inspiring the Industrial Enlightenment. His influence on the Industrial Enlighten- 34
35 ment can be readily ascertained by the deep admiration the encyclopédistes felt toward him, including a long 35
36 article on Baconisme written by the Abbé Pestre and the credit given him by Diderot himself in his entries 36
37 on *Art* and *Encyclopédie*. The *Journal Encyclopédique* wrote in 1756 “If this society owes everything to 37
38 Chancellor Bacon, the philosopher doe not owe less to the authors of the *Encyclopédie*” [cited by Kronick 37
38 (1962, p. 42)]. The great Scottish Enlightenment philosophers Dugald Stewart and Francis Jeffrey agreed on 38
39 Baconian method and goals, even if they differed on some of the interpretation [Chitnis (1976, pp. 214–215)]. 39

40 ²⁸ A typical passage in this spirit was written by the British chemist and philosopher Joseph Priestley (1768, 40
41 p. 7): “If, by this means, one art or science should grow too large for an easy comprehension in a moderate 41
42 space of time, a commodious subdivision will be made. Thus all knowledge will be subdivided and extended, 42
43 and *knowledge* as Lord Bacon observes, being *power*, the human powers will be increased . . . men will make 43
their situation in this world abundantly more easy and comfortable”.

1 was – at least in theory, if not always in practice – the Royal Society, whose initial
2 objectives were inspired by Lord Bacon. Bacon was cited approvingly by many of the
3 leading lights of the Industrial Enlightenment, including Lavoisier, Davy, and the as-
4 tronomer John Herschel [Sargent (1999, pp. xxvii–xxviii)].²⁹

5 Nothing of the sort, I submit, can be detected in the Ottoman Empire, India, Africa,
6 or China. It touched only ever so lightly (and with a substantial delay) upon Iberia,
7 Russia, and South America but in many of these areas it encountered powerful resis-
8 tance and retreated. Invention, as many scholars have rightly stressed, had never been
9 a European monopoly, and much of its technological creativity started with adopting
10 ideas and techniques the Europeans had observed from others [Mokyr (1990)]. The en-
11 lightenment, however, provided the ideological foundation of invention, namely a belief
12 that the understanding of nature was the key to growing control of the physical environ-
13 ment. Moreover, it laid out an agenda on how to achieve this control by demanding that
14 this understanding take the form of general and widely applicable principles. With the
15 success of this program came rising living standards, comfort and wealth. The histori-
16 cal result, then, was that eighteenth century Europe created the ability to break out of
17 the ineluctable concavity and negative feedback that the limitations of knowledge and
18 institutions had set on practically all economies until then. The stationary state was re-
19 placed by the steady state. It is this phenomenon rather than coal or the ghost acreage
20 of colonies that answers Pomeranz’s (2000, p. 48) query why Chinese science and tech-
21 nology – which did not “stagnate” – “did not revolutionize the Chinese economy”.

22 The Industrial Enlightenment can be viewed in part as a movement that insisted on
23 asking not just “*which* techniques work” but also “*why* techniques work” – realizing that
24 such questions held the key to continuing progress. In the terminology introduced above,
25 the intellectuals at its center felt intuitively that constructing and widening an epistemic
26 base for the techniques in use would lead to continuing technological progress. Sci-
27 entists, engineers, chemists, medical doctors, and agricultural improvers made sincere
28 efforts to generalize from the observations they made, to connect observed facts and
29 regularities (including successful techniques) to the formal propositional knowledge of
30 the time, and thus provide the techniques with wider epistemic bases. The bewildering
31 complexity and diversity of the world of techniques in use was to be reduced to a finite
32 set of general principles governing them, or if not, to catalog and classify them in such
33 ways as to make the knowledge more organized and thus easier to access.³⁰ These in-
34 sights would lead to extensions, refinements, and improvements, as well as speed up and
35

36
37 ²⁹ McClellan (1985, p. 52). It should be added that strictu sensu the Royal Society soon allowed in amateurs
38 and dilettantes and thus became less of a pure “Baconian” institution than the French Académie Royale. Dear
39 (1985, p. 147) notes that the Royal Society was “more of a club than a college”.

40 ³⁰ One thinks, of course, above all of the work of Carl Linnaeus. The lack of theory to explain living things
41 similar to physics was acutely felt. Thus Erasmus Darwin, grandfather of the biologist and himself a charter
42 member of the Lunar Society and an archtypical member of the British Industrial Enlightenment, complained
43 in 1800 that Agriculture and Gardening had remained only Arts without a true theory to connect them [Porter
(2000, p. 428)]. For details about Darwin, see especially McNeil (1987) and Uglow (2002).

1 streamline the process of invention.³¹ Asking such questions was of course much easier 1
2 than answering them. In the longer term, however, raising the questions and develop- 2
3 ing the tools to get to the answers were essential if technical progress was not to fizzle 3
4 out.³² The typical enlightenment inventor did more than tinkering and trial-and-error 4
5 fiddling with existing techniques: he tried to relate puzzles and challenges to whatever 5
6 *general* principles could be found, and if necessary to formulate such principles anew. 6
7 To do so, each inventor needed some mode of communication that would allow him to 7
8 tap the knowledge of others. The paradigmatic example of such an inventor remains the 8
9 great James Watt, whose knowledge of mathematics and physics were matched by his 9
10 tight connections to the best scientific minds of his time, above all Joseph Black and 10
11 Joseph Priestley. The list of slightly less famous pioneers of technology who cultivated 11
12 personal connections with scientists can be made arbitrarily long. 12

13 The other side of the Industrial Enlightenment had to do with the diffusion of and 13
14 the access to *existing* knowledge. The *philosophes* realized that, in terms of the frame- 14
15 work outlined above, access costs were crucial and that useful knowledge should not 15
16 be confined to a select few but should be disseminated as widely as possible.³³ Diffu- 16
17 sion needed help, however, and much of the Industrial Enlightenment was dedicated to 17
18 making access to useful knowledge easier and cheaper.³⁴ From the widely-felt need to 18
19 rationalize and standardize weights and measures, the insistence on writing in vernac- 19
20 ular language, to the launching of scientific societies and academies (functioning as de 20
21 facto clearing houses of useful knowledge), to that most paradigmatic Enlightenment 21
22 triumph, the *Grande Encyclopédie*, the notion of diffusion found itself at the center of 22
23 attention among intellectuals.³⁵ Precisely because the Industrial Enlightenment was not 23
24 a national or local phenomenon, it became increasingly felt that differences in language 24
25 and standards became an impediment and increased access costs. Watt, James Keir, 25
26

27
28 ³¹ Somewhat similar views have been expressed recently by other scholars such as John Graham Smith (2001) 28
29 and Picon (2001). 29

30 ³² George Campbell, an important representative of the Scottish Enlightenment noted that “All art [including 30
31 mechanical art or technology] is founded in science and practical skills lack complete beauty and utility when 31
32 they do not originate in knowledge” [cited by Spadafora (1990, p. 31)]. 32

33 ³³ Some Enlightenment thinkers believed that this was already happening in their time: the philosopher and 33
34 psychologist David Hartley believed that “the diffusion of knowledge to all ranks and orders of men, to 34
35 all nations, kindred and tongues and peoples ... cannot be stopped but proceeds with an ever accelerating 35
36 velocity” [cited by Porter (2000, p. 426)]. 36

37 ³⁴ The best summary of this aspect of the Industrial Enlightenment was given by Diderot in his widely-quoted 37
38 article on “Arts” in the *Encyclopédie*: “We need a man to rise in the academies and go down to the workshops 38
39 and gather material about the [mechanical] arts to be set out in a book that will persuade the artisans to read, 39
40 philosophers to think along useful lines, and the great to make at least some worthwhile use of their authority 40
41 and wealth”. 41

42 ³⁵ Roche (1998, pp. 574–575) notes that “if the *Encyclopédie* was able to reach nearly all of society (al- 42
43 though ... peasants and most of the urban poor had access to the work only indirectly), it was because the 43
44 project was broadly conceived as a work of popularization, of useful diffusion of knowledge”. The cheaper 44
45 versions of the Diderot–d’Alembert masterpiece, printed in Switzerland, sold extremely well: the Geneva 45
46 (quarto) editions sold around 8000 copies and the Lausanne (octavo) editions as many as 6000. 46

1 and the Derby clockmaker John Whitehurst, worked on a system of universal terms 1
2 and standards, that would make French and British experiments “speak the same lan- 2
3 guage” [Uglow (2002, p. 357)]. Books on science and technology were translated rather 3
4 quickly, even when ostensibly Britain and France were at war with one another. 4

5 Access costs depended in great measure on knowing what was known, and for that 5
6 search engines were needed. The ultimate search engine of the eighteenth century was 6
7 the encyclopedia. Diderot and d’Alembert’s *Encyclopédie* did not augur the Industrial 7
8 Revolution, it did not predict factories, and had nothing to say about mechanical cot- 8
9 ton spinning equipment or steam engines. It catered primarily to the landowning elite 9
10 and the bourgeoisie of the *ancien régime* (notaries, lawyers, local officials) rather than 10
11 specifically to an innovative industrial bourgeoisie, such as it was. It was, in many ways, 11
12 a conservative document [Darnton (1979, p. 286)]. But the Industrial Enlightenment, as 12
13 embodied in the *Encyclopédie* and similar works that were published in the eighteenth 13
14 century implied a very different way of looking at technological knowledge: instead of 14
15 intuition came systematic analysis, instead of mere dexterity an attempt to attain an un- 15
16 derstanding of the principles at work, instead of secrets learned from a master, an open 16
17 and accessible system of training and learning. It was also a comparatively user-friendly 17
18 compilation, arranged in an accessible way, and while its subscribers may not have been 18
19 mostly artisans and small manufacturers, the knowledge contained in it dripped down 19
20 through a variety of leaks to those who could make use of it.³⁶ Encyclopedias and “dic- 20
21 tionaries” were supplemented by a variety of textbooks, manuals, and compilations of 21
22 techniques and devices that were somewhere in use. The biggest one was probably the 22
23 massive *Descriptions des arts et métiers* produced by the French Académie Royale des 23
24 Sciences.³⁷ Many other specialist compilations of technical and engineering data ap- 24
25 peared.³⁸ In agriculture, meticulously compiled data collections looking at such topics 25
26 as yields, crops, and cultivation methods were common.³⁹ 26
27 27

28 28
29 29
30 ³⁶ Pannabecker points out that the plates in the *Encyclopédie* were designed by the highly skilled Louis- 30
31 Jacques Goussier who eventually became a machine designer at the Conservatoire des arts et métiers in Paris 31
32 [Pannabecker (1996)]. They were meant to popularize the rational systematization of the mechanical arts to 32
33 facilitate technological progress. The parish priest in St. Hubert (in Flanders) traveled to Brussels to purchase 33
34 a copy, since he had heard of its emphasis on technology and was eager to learn of new ways to extract the 34
35 coal resources of his land [Jacob (2001, p. 55)]. 34

35 ³⁷ The set included 13,500 pages of text and over 1,800 plates describing virtually every handicraft practiced 35
36 in France at the time, and every effort was made to render the descriptions “realistic and practical” [Cole and 36
37 Watts (1952, p. 3)]. 36

37 ³⁸ An example is the detailed description of windmills (*Groot Volkomen Moolenboek*) published in the 37
38 Netherlands as early as 1734. A copy was purchased by Thomas Jefferson and brought to North America 38
39 [Davids (2001)]. Jacques-François Demachy’s *l’Art du distillateur d’eaux fortes* (1773) (published as a vol- 39
40 ume in the *Descriptions*) is a “recipe book full of detailed descriptions of the construction of furnaces and the 40
41 conduct of distillation” [John Graham Smith (2001, p. 6)]. 41

42 ³⁹ William Ellis’ *Modern Husbandman or Practice of Farming* published in 1731 gave a month-by-month 42
43 set of suggestions, much like Arthur Young’s most successful book, *The Farmer’s Kalendar* (1770). Most of 43
44 these writings were empirical or instructional in nature, but a few actually tried to provide the readers with 44

1 The Industrial Enlightenment realized instinctively that one of the great sources of 1
2 technological stagnation was a social divide between those who knew things (“savants”) 2
3 and those who made things (“fabricants”). To construct pipelines through which those 3
4 two groups could communicate was at the very heart of the movement.⁴⁰ The rela- 4
5 tionship between those who possessed useful knowledge and those who might find a 5
6 productive use for it was changing in eighteenth-century Europe and points to a reduc- 6
7 tion in access costs. They also served as a mechanism through which practical people 7
8 with specific technical problems to solve could air their needs and thus influence the 8
9 research agenda of the scientists, while at the same time absorbing what best-practice 9
10 knowledge had to offer. The movement of knowledge was thus bi-directional, as seems 10
11 natural to us in the twenty-first century. In early eighteenth-century Europe, however, 11
12 such exchanges were still quite novel. 12

13 An interesting illustration can be found in the chemical industry. Pre-Lavoisier chem- 13
14 istry, despite its limitations, is an excellent example of how *some* knowledge, no matter 14
15 how partial or erroneous, was believed to be of use in mapping into new techniques.⁴¹ 15
16 The pre-eminent figure in this field was probably William Cullen, a Scottish physi- 16
17 cian and chemist. His work “exemplifies all the virtues that eighteenth-century chemists 17
18 believed would flow from the marriage of philosophy and practice” [Donovan (1975, 18
19 p. 84)]. Ironically, this marriage remained barren for many decades. In chemistry the ex- 19
20 pansion of the epistemic base and the flurry of new techniques it generated did not occur 20
21 fully until the mid-nineteenth century [Fox (1998)]. Cullen’s prediction that chemical 21
22 theory would yield the principles that would direct innovations in the practical arts re- 22
23 mained, in the words of the leading expert on eighteenth-century chemistry, “more in 23
24 the nature of a promissory note than a cashed-in achievement” [Golinski (1992, p. 29)]. 24
25 Manufacturers needed to know why colors faded, why certain fabrics took dyes more 25
26

27
28
29 some systematic analysis of the principles at work. One of those was Francis Home’s *Principles of Agriculture* 29
30 *and Vegetation* (1757). One of the great private data collection projects of the time were Arthur Young’s famed 30
31 *Tours* of various parts of England and William Marshall’s series on *Rural Economy* [Goddard (1989)]. They 31
32 collected hundreds of observations on farm practice in Britain and the continent. Although at times Young’s 32
33 conclusions were contrary to what his own data indicated [see Allen and O Gráda (1988)]. 33

34 ⁴⁰ This point was first made by Zilsel (1942) who placed the beginning of this movement in the middle of the 34
35 sixteenth century. While this may be too early for the movement to have much economic effect, the insight 35
36 that technological progress occurs when intellectuals communicate with producers is central to its historical 36
37 explanation. 37

38 ⁴¹ Cullen lectured (in English) to his medical students, but many outsiders connected with the chemical in- 38
39 dustry audited his lectures. Cullen believed that as a philosophical chemist he had the knowledge needed to 39
40 rationalize the processes of production [Donovan (1975, p. 78)]. He argued that pharmacy, agriculture, and 40
41 metallurgy were all “illuminated by the principles of philosophical chemistry” and added that “wherever any 41
42 art [that is, technology] requires a matter endowed with any peculiar physical properties, it is chemical philoso- 42
43 phy which informs us of the natural bodies possessed of these bodies” [cited by Brock (1992, pp. 272–273)]. 43
44 He and his colleagues worked, among others, on the problem of purifying salt (needed for the Scottish fish- 44
45 preservation industry), and that of bleaching with lime, a common if problematic technique in the days before 45
46 chlorine. 46

1 readily than others, and so on, but as late as 1790 best-practice chemistry was inca- 1
2 pable of helping them much [Keyser (1990, p. 222)]. Before the Lavoisier revolution 2
3 in chemistry, it just could not be done, no matter how suitable the social climate: the 3
4 minimum epistemic base simply did not exist. All the same, Cullen personifies a 4
5 social demand for propositional knowledge for economic purposes. Whether or not the 5
6 supply was there, his patrons and audience in the culture of the Scottish Enlightenment 6
7 believed that there was a chance he could [Golinski (1988)] and put their money be- 7
8 hind their beliefs. At times, clever and ingenious people, especially could contribute to 8
9 the solution of problems. The greatest British mathematician of the eighteenth century, 9
10 Colin MacLaurin, was reputed to be at hand to resolve “whatever difficulty occurred 10
11 concerning the construction or perfection of machines, the working of mines, the im- 11
12 provement of manufactures, or the conveying of water” [Murdoch (1750, p. xxiv)]. The 12
13 great French physicist René Réaumur (1683–1757) studied in great detail the properties 13
14 of Chinese porcelain and the physics of iron and steel, and produced over 200 copper 14
15 plates depicting the operation of workshops, machines, and tools of a range of trades 15
16 [Gillispie (1980, pp. 346–347)]. But most of this promise was not realized till after 1800. 16

17 To dwell on one more example, consider the development of steam power. The ambi- 17
18 guities of the relations between James Watt and his mentor, the Scottish scientist Joseph 18
19 Black are well known. Whether or not Watt’s crucial insight of the separate condenser 19
20 was due to Black’s theory of latent heat, there can be little doubt that the give-and-take 20
21 between the scientific community in Glasgow and the creativity of men like Watt was 21
22 essential in smoothing the path of technological progress.⁴² The same was true in the 22
23 South of Britain. Richard Trevithick, the Cornish inventor of the high pressure engine, 23
24 posed sharp questions to his scientist acquaintance Davies Gilbert (later President of the 24
25 Royal Society), and received answers that supported and encouraged his work [Burton 25
26 (2000, pp. 59–60)]. 26

27 The physics of energy remains one of the most striking illustrations of the interactions 27
28 between propositional and prescriptive knowledge. Only in the decades after 1824 did 28
29 the understanding that steam was a heat engine and not a device run by pressure break 29
30 through. The work of Mancunians Joule and Rankine on thermodynamics led to the de- 30
31 velopment of the two cylinder compound marine steam engine and the re-introduction 31
32 of steam-jacketing. It led to a different way of looking at thermal efficiency that drove 32
33 home the insight that no matter how one improved a steam engine, its efficiency would 33
34 always be low – thus pointing the way to internal combustion engines as a solution. Most 34
35

36
37 ⁴² Hills (1989, p. 53) explains that Black’s theory of latent heat helped Watt compute the optimal amount of 37
38 water to be injected without cooling the cylinder too much. More interesting, however, was his reliance on 38
39 William Cullen’s finding that in a vacuum water would boil at much lower, even tepid, temperatures, releasing 39
40 steam that would ruin the vacuum in a cylinder. In some sense that piece of propositional knowledge was 40
41 essential to his realization that he needed a separate condenser. In other areas, too, the discourse between those 41
42 who controlled Ω -knowledge and those who built new techniques was fruitful. Henry Cort, whose invention 42
43 of the puddling and rolling process was no less central than Watt’s separate consenser, also consulted Joseph 43
Black during his work.

1 important, the widening of the epistemic base pointed to what could *not* be done, pre- 1
2 vented inventors and engineers from walking into blind alleys and working on projects 2
3 that were infeasible. John Ericsson’s “regenerative” engine of 1853 was still an attempt 3
4 to “recycle” heat over and over again, before the ineluctable energy-accounting truths 4
5 of thermodynamics had fully sunk in [Bryant (1973)]. Such advances were slow and 5
6 not always monotonic. At times a little knowledge could be a dangerous thing, such 6
7 as theory of latent heat which made many engineers experiment with alternative fluids 7
8 whose physical properties were thought to contain less latent heat.⁴³ 8

9 Some of the most interesting enlightenment figures made a career out of specializing 9
10 in building bridges between propositional and prescriptive knowledge. Among these 10
11 facilitators was William Nicholson, the founder and editor of the first truly scientific 11
12 journal, namely *Journal of Natural Philosophy, Chemistry, and the Arts* (more gener- 12
13 ally known at the time as *Nicholson’s Journal*), which commenced publication in 1797. 13
14 It published the works of most of the leading scientists of the time, and played the role 14
15 of today’s *Nature* or *Science*, that is, to announce important discoveries in short commu- 15
16 nications. In it, leading scientists including John Dalton, Berzelius, Davy, Rumford, and 16
17 George Cayley communicated their findings and opinions.⁴⁴ Another was John Coakley 17
18 Lettsom, famous for being one of London’s most successful and prosperous physicians 18
19 and for liberating his family’s slaves in the Caribbean. He corresponded with many other 19
20 Enlightenment figures including Benjamin Franklin, Erasmus Darwin and the noted 20
21 Swiss physiologist Albrecht von Haller. He wrote about the Natural History of Tea and 21
22 was a tireless advocate of the introduction of mangel wurzel into British agriculture 22
23 Porter (2000, pp. 145–147). A third Briton who fits this description as a mediator be- 23
24 tween the world of propositional knowledge and that of technology was Joseph Banks, 24
25 one of the most distinguished and respected botanists of his time. Banks, a co-founder 25
26 (with Rumford) of the Royal Institution in 1799, was a friend to George III and president 26
27 of the Royal Society for forty two years, every inch an enlightenment figure, devoting 27
28 his time and wealth to advance learning and to use the learning to create wealth, “an 28
29 awfully English *philosophe*” in Roy Porter’s (2000, p. 149) memorable phrase. 29

30 As might be expected, in some cases the bridge between propositional and prescrip- 30
31 tive knowledge occurred within the same mind: the very same people who also were 31
32 32

33 33
34 34
35 ⁴³ The example also points to the importance of tightness as a concept. In the early days of thermodynamic, 35
36 there was still a lot of confusion about what was and was not feasible. Bryant (1973, p. 161) notes that “it 36
37 seems strange that inventors [such as Ericsson] operating on what seems to us a pretty shaky theory were able 37
38 to get financial support”. The answer is that at that early stage of the theory, an authority on heat engines could 38
39 be perfectly sound on thermodynamics yet still be uncertain when faced by a complicated engine supported 39
40 by “data”. 39

40 ⁴⁴ Nicholson also was a patent agent, representing other inventors, and around 1800 ran a “scientific estab- 40
41 lishment for pupils” on London’s Soho square. The school’s advertisement ran that “this institution affords a 41
42 degree of practical knowledge of the sciences which is seldom acquired in the early part of life” delivering 42
43 weekly lectures on natural philosophy and chemistry “illustrated by frequent exhibition and explanations of 42
44 the tools, processes and operations of the useful arts and common operations of society”. 43

1 contributing to science made some critical inventions (even if the exact connection be- 1
2 tween their science and their ingenuity is not always clear). The importance of such 2
3 dual or “hybrid” careers, as Eda Kranakis (1992) has termed them, is that access to 3
4 the propositional knowledge that could underlie an invention is immediate, as is the 4
5 feedback from technological advances to propositional knowledge. In most cases the 5
6 technology shaped the propositional research as much as the other way around. The idea 6
7 that those contributing to propositional knowledge should specialize in research and 7
8 leave its “mapping” into technology to others had not yet ripened. Among the inven- 8
9 tions made by people whose main fame rests on their scientific accomplishments were 9
10 the chlorine bleaching process invented by the chemist Claude Berthollet, the invention 10
11 of carbonated (sparkling) water and rubber erasers by Joseph Priestley, and the mining 11
12 safety lamp invented by the leading scientist of his age, Humphry Davy (who also, inci- 12
13 dentally, wrote a textbook on agricultural chemistry and discovered that a tropical plant 13
14 named *catechu* was a useful additive to tanning).⁴⁵ 14

15 Typical of the “dual career” phenomenon was Benjamin Thompson (later Count 15
16 Rumford, 1753–1814), an American-born mechanical genius who was on the loyal- 16
17 ist side during the War of Independence and later lived in exile in Bavaria, London, 17
18 and Paris; he is most famous for the scientific proof that heat is not a liquid (known at 18
19 the time as *caloric*) that flows in and out of substances. Yet Rumford was deeply in- 19
20 terested in technology, helped establish the first steam engines in Bavaria, and invented 20
21 (among other things) the drip percolator coffeemaker, a smokeless-chimney stove, and 21
22 an improved oil lamp. He developed a photometer designed to measure light intensity 22
23 and wrote about science’s ability to improve cooking and nutrition [G.I. Brock (1992, 23
24 pp. 95–110)]. Rumford is as good a personification of the Industrial Enlightenment as 24
25 one can find. Indifferent to national identity and culture, Rumford was a “Westerner” 25
26 whose world spanned the entire northern Atlantic area (despite being an exile from the 26
27 United States, he left much of his estate to establish a professorship at Harvard). In 27
28 that respect he resembled his older compatriot inventor Benjamin Franklin, who was as 28
29 celebrated in Britain and France as he was in his native Philadelphia. Rumford could 29
30 map from his knowledge of natural phenomena and regularities to create things he 30
31 deemed useful for mankind [Sparrow (1964, p. 162)].⁴⁶ Like Franklin and Davy, he 31
32 refused to take out a patent on any of his inventions – as a true child of the Enlight- 32
33 enment he was committed to the concept of open and free knowledge.⁴⁷ Instead, he 33
34 34
35 35

36 ⁴⁵ It is unclear how much of the best-practice science was required for the safety lamp, and how much 36
37 was already implied by the empirical propositional knowledge accumulated in the decades before 1815. It is 37
38 significant that George Stephenson, of railway fame, designed a similar device at about the same time. 38

39 ⁴⁶ It is telling that Rumford helped found the London Royal Institute in 1799. This institute was explicitly 39
40 aimed at the diffusion of useful knowledge to wider audiences through lectures. In it the great Humphry Davy 40
41 and his illustrious pupil Michael Faraday gave public lectures and did their research. 41

42 ⁴⁷ The most extreme case of a scientist insisting on open and free access to the propositional knowledge he 42
43 discovered was Claude Berthollet, who readily shared his knowledge with James Watt, and declined an offer 43
by Watt to secure a patent in Britain for the exploitation of the bleaching process [J.G. Smith (1979, p. 119)].

1 felt that honor and prestige were often a sufficient incentive for people to contribute 1
2 to useful knowledge. He established the Rumford medal, to be awarded by the Royal 2
3 Society “in recognition of an outstandingly important recent discovery in the field of 3
4 thermal or optical properties of matter made by a scientist working in Europe, noting 4
5 that Rumford was concerned to see recognised discoveries that tended to promote the 5
6 good of mankind”. Not all scientists eschewed such profits: the brilliant Scottish aris- 6
7 tocrat Archibald Cochrane (Earl of Dundonald) made a huge effort to render the coal 7
8 tar process he patented profitable, but failed and ended up losing his fortune. Incentives 8
9 were, as always, central to the actions of the figures of the Industrial Enlightenment, but 9
10 we should not assume that these incentives were homogeneous and the same for all. 10

11 The other institutional mechanism emerging during the Industrial Enlightenment to 11
12 connect between those who possessed prescriptive knowledge and those who wanted 12
13 to apply it was the emergence of meeting places where men of industry interacted with 13
14 natural philosophers. So-called scientific societies, often known confusingly as literary 14
15 and philosophical societies, sprung up everywhere in Europe. They organized lectures, 15
16 symposia, public experiments, and discussion groups, in which the topics of choice 16
17 were the best pumps to drain mines, or the advantages of growing clover and grass.⁴⁸ 17
18 Most of them published some form of “proceedings”, as often meant to popularize and 18
19 diffuse existing knowledge as it was to display new discoveries. Before 1780 most of 19
20 these societies were informal and ad hoc, but they eventually became more formal. 20
21 The British Society of Arts, founded in 1754, was a classic example of an organization 21
22 that embodied many of the ideals of the Industrial Enlightenment. Its purpose was “to 22
23 embolden enterprise, to enlarge science, to refine art, to improve manufacture and to 23
24 extend our commerce”. Its activities included an active program of awards and prizes 24
25 for successful inventors: over 6,200 prizes were granted between 1754 and 1784.⁴⁹ The 25
26 society took the view that patents were a monopoly, and that no one should be excluded 26
27 from useful knowledge. It therefore ruled out (until 1845) all persons who had taken 27
28 out a patent from being considered for a prize and even toyed with the idea of requiring 28
29 every prize-winner to commit to never take out a patent.⁵⁰ It served as a communications 29
30 network and clearing house for technological information, reflecting the feverish growth 30
31 of supply and demand for useful knowledge. 31
32

33 What was true for Britain was equally true for Continental countries affected by 33
34 the Enlightenment. In the Netherlands, rich but increasingly technologically backward, 34
35 heroic efforts were made to set up organizations that could infuse the economy with 35
36

37
38
39 ⁴⁸ The most famous of these societies were the Manchester Literary and Philosophical Society (founded 39
40 in 1781) and the Birmingham Lunar Society, where some of the great entrepreneurs and engineers of the 40
41 time mingled with leading chemists, physicists, and medical doctors. But in many provincial cities such as 41
42 Liverpool, Hull and Bradford, a great deal of similar activity took place. 42

⁴⁹ For details see Wood (1913) and Hudson and Luckhurst (1954). 42

⁵⁰ Hilaire-Pérez (2000, p. 197), Wood (1913, pp. 243–245). 43

1 more innovativeness.⁵¹ In Germany, provincial academies to promote industrial, agri- 1
2 cultural, and political progress through science were founded in all the significant 2
3 German states in the eighteenth century. The Berlin Academy was founded in 1700 3
4 and in its early years directed by the great Leibniz, and among its achievements was 4
5 the discovery that sugar could be extracted from beets (1747). Around 200 societies ap- 5
6 peared during the half-century spanning from the Seven-Years War to the climax of the 6
7 Napoleonic occupation of Germany, such as the Patriotic Society founded at Hamburg 7
8 in 1765 [Lowood (1991, pp. 26–27)]. These societies, too, emphasized the welfare of 8
9 the population at large and the country over private profit. Local societies supplemented 9
10 and expanded the work of learned national academies.⁵² Publishing played an impor- 10
11 tant role in the work of societies bent on the encouragement of invention, innovation 11
12 and improvement. This reflected the emergence of open knowledge, a recognition that 12
13 knowledge was a non-rivalrous good the diffusion of which was constrained by access 13
14 costs. 14

15 In France, great institutions were created under royal patronage, above all the 15
16 *Académie Royale des Sciences*, created by Colbert and Louis XIV in 1666 to dissem- 16
17 inate information and resources.⁵³ Yet the phenomenon was nationwide: 33 official 17
18 learned societies were functioning in the French provinces during the eighteenth century 18
19 19

20 20
21 ⁵¹ The first of these was established in Haarlem in 1752, and within a few decades the phenomenon spread 21
22 much like in England to the provincial towns. The Scientific Society of Rotterdam known oddly as the *Batavic* 22
23 *Association for Experimental Philosophy* was the most applied of all, and advocated the use of steam engines 23
24 (which were purchased in the 1770s but without success). The Amsterdam Society was known as *Felix Meritis* 24
25 and carried out experiments in physics and chemistry. These societies stimulated interest in physical and 25
26 experimental sciences in the Netherlands, and they organized prize-essay contests on useful applications of 26
27 natural philosophy. A physicist named Benjamin Bosma for decades gave lectures on mathematics, geography, 27
28 and applied physics in Amsterdam. A Dutch Society of Chemistry founded in the early 1790s helped to 28
29 convert the Dutch to the new chemistry proposed by Lavoisier [Snelders (1992)]. The Dutch high schools, 29
30 known as *Athenea* taught mathematics, physics, astronomy, and at times counted distinguished scientists 30
31 among their staff. 31

32 ⁵² The German local societies were private institutions, unlike state-controlled academies, which enabled 32
33 them to be more open, with few conditions of entry, unlike the selective, elitist academies. They broke down 33
34 social barriers, for the established structures of Old Regime society might impede useful work requiring a 34
35 mixed contribution from the membership of practical experience, scientific knowledge, and political power. 35
36 Unlike the more scientifically-inclined academies, they invited anyone to join, such as farmers, peasants, 36
37 artisans, craftsmen, foresters, and gardeners, and attempted to improve the productivity of these occupations 37
38 and solve the economic problems of all classes. Prizes rewarded tangible accomplishments, primarily in the 38
39 agricultural or technical spheres. Their goal was not to advance learning like earlier academies, but to apply 39
40 useful results of human knowledge, discovery and invention to practical and civic life [Lowood (1991)]. 40
41 41

42 ⁵³ It was one of the oldest and financially best supported scientific societies of the eighteenth century, with 42
43 a membership which included d'Alembert, Buffon, Clairaut, Condorcet, Fontenelle, Laplace, Lavoisier and 43
44 Reaumur. It published the most prestigious and substantive scientific series of the century in its annual pro- 44
45 ceedings *Histoire et Memoires* and sponsored scientific prize contests such as the Meslay prizes. It recognized 45
46 achievement and rewarded success for individual discoveries and enhanced the social status of scientists, 46
47 granting salaries and pensions. A broad range of scientific disciplines were covered, with mathematics and 47
48 astronomy particularly well represented, as well as botany and medicine. 48

1 counting over 6,400 members. Overall, [McClellan \(1981, p. 547\)](#) estimates that during 1
2 the century perhaps between 10,000 and 12,000 men belonged to learned societies that 2
3 dealt at least in part with science. The *Académie Royale* exercised a fair amount of con- 3
4 trol over the direction of French scientific development and acted as technical advisor to 4
5 the monarchy. By determining what was published and exercising control over patents, 5
6 the *Académie* became a powerful administrative body, providing scientific and techni- 6
7 cal advice to government bureaus. France, of course, had a somewhat different objective 7
8 than Britain: it is often argued that the *Académie* linked the aspirations of the scientific 8
9 community to the utilitarian concerns of the government creating not a Baconian so- 9
10 ciety open to all comers and all disciplines but a closed academy limited primarily to 10
11 Parisian scholars [[McClellan \(1981\)](#)]. Yet the difference between France and Britain 11
12 was one of emphasis and nuance, not of essence: they shared a utilitarian optimism of 12
13 mankind's ability to create wealth through knowledge. In other parts of Europe, such as 13
14 Italy, scientific societies were active in the eighteenth century [[Inkster \(1991, p. 35\)](#) and 14
15 [Cochrane \(1961\)](#)]. At the level of the creation of propositional knowledge, at least, there 15
16 is little evidence that the *ancien régime* was incapable of generating sustained progress. 16

17 To summarize, then, the Industrial Revolution had intellectual preconditions that 17
18 needed to be met if sustained economic growth could take place just as it had to sat- 18
19 isfy economic and social conditions. The importance of property rights, incentives, 19
20 factor markets, natural resources, law and order, market integration, and many other 20
21 economic elements is not in question. But we need to realize that without understanding 21
22 the changes in attitudes and beliefs of the key players in the growth of useful knowledge, 22
23 the technological elements will remain inside a black box. 23
24

25 26 **6. The dynamic of technological modernity** 26 27

28 The essence of technological modernity is non-stationarity: many scholars have ob- 28
29 served that technological change has become self-propelled and autocatalytic, in which 29
30 change feeds on change. Unlike other forms of growth, spiraling technological progress 30
31 does not appear to be bounded from above. Predictions in the vein of "everything that 31
32 can be invented already has been" have been falsified time and again. The period that 32
33 followed the Industrial Revolution was one in which innovation intensified, and while 33
34 we can discern a certain ebb and flow, in which major breakthroughs and a cluster of 34
35 macroinventions were followed by waves of microinventions and secondary extensions 35
36 and applications, the dynamic has become non-ergodic, that is to say, the present and the 36
37 future are nothing like the past. In the premodern past, whether in Europe or elsewhere 37
38 in the world, invention had remained the exception, if perhaps not an uncommon one. 38
39 In the second half of the nineteenth century and even more so in the twentieth century, 39
40 change has become the norm, and even in areas previously untouched by technological 40
41 innovation, mechanization, automation, and novelty have become inevitable. There is 41
42 no evidence to date that technology in its widest sense converges to anything. 42
43

1 To oversimplify, the Industrial Revolution could be reinterpreted in light of the 1
2 changes in the characteristics and structure of propositional knowledge in the eighteenth 2
3 century and the techniques that rested on it. Before 1750 the human race, as a collec- 3
4 tive, did not know enough to generate the kind of sustained technological progress that 4
5 could account for the growth rates we observe. In the absence of such knowledge, no set 5
6 of institutions, no matter how benevolent, could have substituted for useful knowledge. 6
7 Pre-modern society had always been limited by its epistemic base and suppressed by 7
8 economic and social factors. The dynamics of knowledge itself were critical to the his- 8
9 torical process. The Industrial Revolution can be seen as what physicists call a “phase 9
10 transition”.⁵⁴ Useful knowledge in the decades that followed increased by feeding on 10
11 itself, spinning out of control as it were. 11

12 How do we explain this change in technological dynamic? In economics, phase trans- 12
13 sitions can be said to occur when a dynamic system has multiple steady states such as 13
14 an economy that has a “poverty trap” (low-income equilibrium) and a high income (or 14
15 rapid growth steady state). A phase transition occurs when the system switches from one 15
16 equilibrium or regime to another. A simple model in which this can be illustrated is one 16
17 in which capital and skills are highly complementary. In such models one equilibrium 17
18 is characterized by rapid investment, which raises the demand for skills; the positive 18
19 feedback occurs because the increase in the rate of return to human capital induces 19
20 parents to invest more in their children, have fewer children (since they become more 20
21 expensive), which raises the rate of return on physical capital even more and encourages 21
22 investment. A second equilibrium is one of low investment, low skills, and high birth 22
23 rates. A regime change may occur when an exogenous shock is violent enough to bump 23
24 the system off one basin of attraction and move it to another one. The difficulty with this 24
25 model for explaining the emergence of modern growth is to identify a historical shock 25
26 that was sufficiently powerful to “bump” the system to a rapid growth trajectory. 26

27 Recent work in growth theory have produced a class of models that reproduce this 27
28 feature in one form or another. [Cervellati and Sunde \(2002\)](#) for example assume that 28
29 human capital comes in two forms, a “theoretical” form and a “practical” form, corre- 29
30 sponding roughly to “scientific” and “artisanal” knowledge or the categories of useful 30
31 knowledge proposed above. They assume that human abilities are heterogeneous but 31
32 that there is a threshold at which people start to invest in “theoretical” knowledge as 32
33 opposed to “crafts”, endogenously determined by life expectancy. This threshold level 33
34 depends on the costs of acquiring the two types of human capital, their respective rates 34
35 of return, and the life expectancy over which they are amortized. Further, they model the 35
36 relationship between mortality and human capital investment. This is a little explored 36
37 aspect of modernization, but one that must have been of some importance. All other things 37
38 equal, longer life expectancy would encourage investment in human capital, although it 38
39 is important to emphasize that a reduction in infant mortality would not directly bring 39
40 this about, because decisions about human capital are made later in life. Increases in life 40
41

42
43 ⁵⁴ For a definition of phase transitions, see for instance [Ruelle \(1991, pp. 122–123\)](#). 41
42
43

1 expectancy at age 10 or so are more relevant here. Given their assumptions, the locus of 1
2 points in the life-expectancy-ability space that define an intra-generational equilibrium 2
3 is S-shaped. A second relationship in this model is that life expectancy itself depends on 3
4 the level of education of the previous generation: better educated parents will be better 4
5 situated to help their children survive. The model is closed by postulating a relationship 5
6 between the high-quality human capital and total productivity. The neat aspect of the 6
7 Cervellati–Sunde model is that if for some reason the productivity of the high-quality 7
8 human capital rises, it produces the kind of observed phase transition when the old 8
9 poverty trap is no longer an equilibrium and the system abruptly starts to move to a new 9
10 “high-level” equilibrium. An exogenous disturbance that raises the marginal productiv- 10
11 ity of “scientific activity” will have the same effect, including an exogenous increase 11
12 in the stock of propositional knowledge and an ideologically-induced change in the re- 12
13 search agenda. Clearly, then, the Industrial Enlightenment, much like an endogenous 13
14 growth in productivity, can produce an “Industrial Revolution” of this type. While un- 14
15 der the assumptions of their paper an Industrial Revolution is “inevitable”, the authors 15
16 recognize that if technological progress has stochastic elements, this could imply a dif- 16
17 ferent prediction (p. 23). Either way, however, the emergence of technologically-based 17
18 “modern growth” can be understood without the need for a sudden violent shock. 18

19 The alternative is to presume that historical processes cause the underlying parame- 19
20 ters to change slowly but cumulatively, until one day what was a slow-growth steady 20
21 state is no longer an equilibrium at all and the system, without a discernible shock, 21
22 moves rather suddenly into a very different steady state. These models, pioneered by 22
23 Galor and Weil (2000), move from comparative statics with respect to a parameter de- 23
24 termining the dynamic structure, to a dynamical system in which this parameter is a 24
25 latent state variable that evolves and ultimately can generate a phase transition.⁵⁵ In the 25
26 Galor–Weil model, the economic *ancien régime* is not really a steady state but a “pseudo 26
27 steady state” despite its long history: within a seeming stability the seeds for the phase 27
28 transition are germinating invisibly. 28

29 A similar model, in which technology plays a “behind the scenes” role, is the highly 29
30 original and provocative model by Galor and Moav (2002). In that model, the phase 30
31 transition is generated by evolutionary forces and natural selection. The idea is that 31
32 there are two classes of people, those who have many children (*r*-strategists) and oth- 32
33 ers (*K*-strategists) who have relatively few but “high-quality” offspring and who invest 33
34 more in education. When “quality types” are selected for, more smart and creative peo- 34
35 ple are added and technology advances. Technological progress increases the rate of 35
36 36

37 37
38 ⁵⁵ Another example of this type of “phase transition” has been proposed recently by David (1998). He 38
39 envisages the community of “scientists” to consist of local networks or “invisible colleges” in the business of 39
40 communicating with each other. Such transmission between connected units can be modeled using percola- 40
41 tion models in which information is diffused through a network with a certain level of connectivity. David 41
42 notes that these models imply that there is a minimum level of persistently communicative behavior that a net- 42
43 work must maintain for knowledge to diffuse through and that once this level is achieved the system becomes 43
self-sustaining.

1 return to human capital, induces more people to have more “high quality” (educated) 1
2 children which provides the positive feedback loop. Moreover, as income advances, 2
3 households have more resources to spend on education, which add to further expansion. 3
4 Again, technology in this model is wholly endogenous to education and investment in 4
5 human capital, and an autonomous development in the social factors governing human 5
6 knowledge and the interplay between propositional and prescriptive knowledge is not 6
7 really modeled. Despite the somewhat limiting assumptions of this model (the “type” 7
8 is purely inherited and not a choice variable), this paper presents an innovative way of 8
9 looking at the problem of human capital formation and economic growth in the histori- 9
10 cal context of the Industrial Revolution. 10

11 In some sense Galor and Moav’s reliance on evolutionary logic to explain technolog- 11
12 ical progress is ironic. In recent years it has been realized increasingly that knowledge 12
13 *itself* is subject to evolutionary dynamics, in that new ideas and knowledge emerge 13
14 much like evolutionary innovations (through mutations or recombinations) and are 14
15 selected for (or not). Knowledge systems follow a highly path-dependent trajectory 15
16 governed by Darwinian forces [Ziman (2000) and Mokyr (2003a)]. Yet this impor- 16
17 tant insight still awaits to be incorporated in the “take-off” models of growth theorists. 17
18 Evolutionary models predict that sudden accelerations or “explosions” of evolutionary 18
19 change (known oddly as “adaptive radiation”) occur when conditions are ripe, such as 19
20 the so-called Cambrian explosion which has been compared to the Industrial Revolu- 20
21 tion [Kauffman (1995, p. 205)]. Another example of rapid evolutionary innovation is the 21
22 spectacular proliferation of mammals at the beginning of the Cenozoic after the disap- 22
23 pearance of the giant reptiles. The idea that evolution proceeds in the highly non-linear 23
24 rhythm known as “punctuated equilibrium” has been suggested as a possible insight that 24
25 economic historians can adapt from evolutionary biology [Mokyr (1990)]. 25

26 Some of these (and other, similar) models may be more realistic than others, and 26
27 economic historians may have to help to sort them out. A phase transition model with- 27
28 out reliance on the quality of children and human capital is proposed by Charles Jones 28
29 (2001) relying on earlier work by Michael Kremer (1993). In Jones’ model, what mat- 29
30 ters is the size rather than the quality of the labor force. In very small populations, the 30
31 few new technological ideas lead in straightforward Malthusian fashion to higher pop- 31
32 ulations and not to higher income per capita. As the population gets larger and larger 32
33 and the number of creative individuals increases, however, new ideas become more and 33
34 more frequent, and productivity pulls ahead. The model assumes increasing returns in 34
35 population and thus generates a classic multiple equilibria kind of story. The positive 35
36 feedback thus works through fertility behavior responding to higher productivity, and 36
37 through an increasing returns to population model. As per capita consumption increases, 37
38 parents substitute away from children to consume other goods, and fertility eventually 38
39 declines. In this fashion these models succeed in generating both a sudden and discon- 39
40 tinuous growth of income per capita or consumption and the fertility transition. Jones 40
41 shows that for reasonable parameter values he can simulate a world economy that re- 41
42 produces the broad outlines of modern economic history (including an initial rise in 42
43 fertility in the early stages of the Industrial Revolution, followed by a decline). 43

1 Yet the exact connection between demographic changes and the economic changes 1
2 in the post 1750 period are far from understood, and much of the new growth literature 2
3 pays scant attention to many variables that surely must have affected the demand for 3
4 children and fertility behavior. These include technological changes in contraceptive 4
5 technology, a decline in infant and child mortality, and changing demand for children in 5
6 the household economy due to technological changes in agriculture and manufacturing. 6
7 It is also open to question whether and to what extent “numbers matter”, that is, whether 7
8 the more people are around, the more likely – all other things equal – new technological 8
9 ideas are to emerge.⁵⁶ The real question is whether the ideas that count are really a 9
10 monotonic function of population size (Jones assumes a positive elasticity of 0.75 to 10
11 generate his results), or whether they are generated by a negligible minority and that 11
12 small changes in the fraction of creative people matters more than a rise in the raw size 12
13 of population.⁵⁷ The historical record on that is subject to serious debate. It might be 13
14 added that population growth in Britain was almost nil in the first half of the eighteenth 14
15 century, and while it took off during the post 1750 era, the same was true for Ireland, 15
16 where no Industrial Revolution of any kind can be detected. 16

17 Most endogenous growth historical models, however, depend on the notion that the 17
18 variable critical to the process of “take-off” or phase transition is investment in human 18
19 capital.⁵⁸ Historically, however, such a view is not unproblematic either. The idea that 19
20 the fertility reduction was a consequence of changing rates of return on human capital, 20
21 especially advanced by Lucas (2002), runs into what may be called the European 21
22 Fertility Paradox: the first nation to clearly reduce its fertility rate through a decline 22
23 in marital fertility (that is, intentional and conscious behavior) was *not* the country in 23
24 which advanced technological techniques were adopted in manufacturing, but France. In 24
25 Britain fertility rates come down eventually, but the decline does not start until the mid- 25
26 1870s, a century after the beginning of the Industrial Revolution [e.g., Tranter (1985, 26
27 chapter 4)]. Imperial Germany, which became the technological leader in many of the 27
28 cutting-edge industries of the second Industrial Revolution, maintained a fertility rate 28
29 far above France’s and Britain’s.⁵⁹ To argue, therefore, that technological progress was 29
30 rooted in demographic behavior (through smaller families) seems at variance with the 30
31 facts. It may well be that in the twentieth century this nexus held, but given the decline 31
32 in wage premia it is hard to see the rate of return on human capital to be the driving fac- 32
33 tor. Beyond Europe, of course, population-driven theories of the “the-more-the-merrier” 33
34 34

35 ⁵⁶ The pedigree of this idea clearly goes back to the work of Julian Simon (1977, 2000). 35

36 ⁵⁷ This sensitivity is reflected in Jones’ simulations: the proportion inventors in the population in 1700 in 36
37 his computations (set to match the demographic data) is 0.875%, but it *declines* in 1800 to less than half 37
38 that number. By constraining the twentieth century data to stay at that level, Jones shows that the Industrial 38
39 Revolution would be delayed by 300 years. 39

40 ⁵⁸ For a similar view advanced by an economic historian before the new growth economics, see Easterlin 40
41 (1981). 41

42 ⁵⁹ In 1900, the total fertility rate (average number of children per woman) in Germany was 4.77, contrasting 42
43 with 3.40 and 2.79 in England and France respectively. By that time, to be sure, German fertility rates were 43
falling rapidly as they were elsewhere in the industrialized world. See e.g. Livi Bacci (2000, p. 136).

1 variety must confront the difficult fact that China not only had a population vastly larger 1
2 than any European economy but that its population grew at a rapid rate in the very cen- 2
3 tury that Europe experienced its Enlightenment: from a low point of about 100 million 3
4 in 1685, it exceeded 300 million in 1790, a per annum growth of 1.05 percent, though 4
5 admittedly from an unusually low base. 5

6 To understand the “phase transition” within the dynamic of useful knowledge, we 6
7 need to look again at the relationship between propositional and prescriptive knowledge. 7
8 As the two forms of knowledge co-evolved, they increasingly enriched one another, 8
9 eventually tipping the balance of the feedback mechanism from negative to positive and 9
10 creating the phase transition. During the early stages of the Industrial Revolution propo- 10
11 sitional knowledge mapped into new techniques creating what we call “inventions”. 11
12 This mapping should not be confused with the linear models of science and technol- 12
13 ogy, popular in the mid-twentieth century, which depicted a neat flow from theory to 13
14 applied science to engineering and from there to technology. Much of the propositional 14
15 knowledge that led to invention in the eighteenth century was artisanal and mechanical, 15
16 pragmatic, informal, intuitive, and empirical. Only very gradually did the kind of formal 16
17 and consensual knowledge we think of today as “science” become a large component 17
18 of it. It was, in all cases, a small fraction of what is known today. What matters is that 18
19 it was subject to endogenous expansion: prescriptive knowledge in its turn enhanced 19
20 propositional knowledge, and thus provided positive feedback between the two types of 20
21 knowledge, leading to continuous mutual reinforcement. When powerful enough, this 21
22 mechanism can account for the loss of stability of the entire system and for continuous 22
23 unpredictable change. 23

24 The positive feedback from prescriptive to propositional knowledge took a variety of 24
25 forms. One of those forms is what Rosenberg has called “focusing devices”: technology 25
26 posed certain riddles that science was unable to solve, such as “why (and how) does this 26
27 technique work”. It has been suggested, for instance that the sophisticated waterworks 27
28 that supplied power to the famous Derby silk mills established by the Lombe brothers 28
29 in the 1710s stimulated local scientists interested in hydraulics and mechanics [Elliott 29
30 (2000, p. 98)]. The most celebrated example of such a loop is the connection between 30
31 steam power and thermodynamics, exemplified in the well-known tale of Sadi Carnot’s 31
32 early formulation, in 1824, of the Second Law of Thermodynamics by watching the 32
33 difference in fuel economy between a high pressure (Woolf) steam engine and a low 33
34 pressure one of the Watt type.⁶⁰ The next big step was made by an Englishman, James 34
35 P. Joule, who showed the conversion rates from work to heat and back.⁶¹ Joule’s work 35
36 36

37 37
38 ⁶⁰ It is interesting to note that Carnot’s now famous *Reflexions sur la puissance motrice du feu* (1824) was 38
39 initially ignored in France and eventually found its way second hand and through translation into Britain, 39
40 where there was considerably more interest in his work because of the growing demand by builders of gigantic 40
41 steam engines such as William Fairbairn in Manchester and Robert Napier in Glasgow for theoretical insights 41
42 that would help in making better engines. 42

43 ⁶¹ The ways in which the growth of practical knowledge can influence the emergence of propositional knowl- 43
edge are well illustrated by Joule’s career: he was a child of industrial Lancashire (his father owned a brewery)

1 and that of Carnot were then reconciled by a German, R.J.E. Clausius (the discoverer of 1
2 entropy), and by 1850 a new branch of science dubbed “thermodynamics” by William 2
3 Thomson (later Lord Kelvin) had emerged [Cardwell (1971, 1974)].⁶² Power technol- 3
4 ogy and classical energy physics subsequently developed cheek by jowl, culminating 4
5 in the career of the Scottish physicist and engineer William Rankine whose *Manual* 5
6 *of the Steam Engine* (1859) made thermodynamics accessible to engineers and led to 6
7 a host of improvements in actual engines. In steam power, then, the positive feedback 7
8 can be clearly traced: the first engines had emerged in the practical world of skilled 8
9 blacksmiths, millwrights, and instrument makers with only a minimum of theoretical 9
10 understanding. These machines then inspired theorists to come to grips with the natural 10
11 regularities at work and to widen the epistemic base. The insights generated were in 11
12 turn fed back to engineers to construct more efficient engines. This kind of mutually 12
13 reinforcing process can be identified, in a growing number of activities, throughout the 13
14 nineteenth century. They required the kind of intellectual environment that the Indust- 14
15 rial Enlightenment had created: a world in which technical knowledge was accessible 15
16 and communicable in an international elite community, a technological invisible college 16
17 that encompassed much of the Western world. 17

18 A less well-known example of this feedback mechanism, but equally important to 18
19 economic welfare, is the interaction between the techniques of food-canning and the 19
20 evolution of bacteriology. As noted earlier, the canning of food was invented in 1795, by 20
21 Nicolas Appert.⁶³ He discovered that when he placed food in champagne bottles, corked 21
22 them loosely, immersed them in boiling water, and then hammered the corks tight, the 22
23 food was preserved for extended periods. Neither Appert nor his English emulators who 23
24 perfected the preservation of food in tin-plated canisters in 1810 really understood why 24
25 and how this technique worked, because the definitive demonstration of the notion that 25
26 microorganisms were responsible for putrefaction of food was still in the future. It is 26
27 therefore a typical example of a working technique with a narrow epistemic base. The 27
28 canning of food led to a prolonged scientific debate about what caused food to spoil. 28
29 The debate was not put to rest until Pasteur’s work in the early 1860s. Pasteur claimed 29
30 ignorance of Appert’s experimental work, but eventually admitted that his own work 30
31 31

32 32
33 and in the words of one historian, “with his hard-headed upbringing in industrial Manchester, was unambigu- 33
34 ously concerned with the *economic* efficiency of electromagnetic engines ... he quite explicitly adopted the 34
35 language and concerns of the economist and the engineer” [Morus (1998, p. 187), emphasis in original]. As 35
36 Ziman (1976, p. 26) remarks, the first law of thermodynamics could easily have been derived from Newton’s 36
37 dynamics by mathematicians such as Laplace or Lagrange, but it took the cost accountancy of engineers to 37
38 bring it to light. 38

39 ⁶² Research combining experiment and theory in thermodynamics continued for many decades after that, 39
40 especially in Scotland and in Mulhouse, France, where Gustave Adolphe Hirn, a textile manufacturer, led 40
41 a group of scientists in tests on the steam engines in his factory and was able to demonstrate the law of 41
42 conservation of energy. 42

43 ⁶³ Experimental work by, among others, the Italian naturalist Lazzaro Spallanzani, had earlier indicated that 43
44 heating organic materials and subsequent airtight flashing would prevent putrefaction. It is unclear whether 44
45 Appert and his British imitators knew of this work. See Clow and Clow (1952, p. 571). 45

1 on the preservation of wine was only a new application of Appert's method. Be that 1
2 as it may, his work on the impossibility of spontaneous generation clearly settled the 2
3 question of why the technique worked and provided the epistemic base for the technique 3
4 in use. When the epistemic base of food-canning became wider, techniques improved: 4
5 the optimal temperatures for the preservation of various foods with minimal damage to 5
6 flavor and texture were worked out by two MIT scientists, Samuel Prescott and William 6
7 Underwood.⁶⁴ 7

8 A different feedback mechanism from prescriptive to propositional knowledge was 8
9 described by Derek Price as "Artificial Revelation". The idea is fairly simple: our senses 9
10 limit us to a fairly narrow slice of the universe that has been called a "mesocosm": we 10
11 cannot see things that are too far away, too small, or not in the visible light spectrum 11
12 [Wuketits (1990, pp. 92, 105)]. The same is true for our other senses, for the ability 12
13 to make very accurate measurements, for overcoming optical and other sensory illu- 13
14 sions, and – perhaps most important in our own time – the computational ability of 14
15 our brains. Technology consists in part in helping us overcome these limitations that 15
16 evolution has placed on us and learn of natural phenomena we were not meant to see or 16
17 hear.⁶⁵ The period of the Industrial Revolution witnessed a great deal of improvement in 17
18 techniques whose purpose it was to enhance propositional knowledge. The great potter 18
19 Josiah Wedgwood maintained a close relationship with the chemist James Keir: while 19
20 Keir supplied Wedgwood with counsel, Wedgwood's factory provided Keir with the 20
21 tubes and retorts he used in his laboratory near Birmingham [Stewart (2004, p. 18)]. The 21
22 accuracy of instruments that measured time, distance, weight, pressure, temperature and 22
23 so on increased by orders of magnitude in the eighteenth century.⁶⁶ Pumps and electri- 23
24 cal machines allowed the study of vacuums and electrical phenomena. Lavoisier and his 24
25 circle were especially good in designing and utilizing better laboratory equipment that 25
26 allowed them to carry out more sophisticated experiments.⁶⁷ Alessandro Volta invented 26
27 a pile of alternating silver and zinc disks that could generate an electric current in 1800. 27
28

29
30 ⁶⁴ A University of Wisconsin scientist, H.L. Russell, proposed to increase the temperature of processing peas 29
31 from 232° to 242°, thus reducing the percentage spoiled can from 5 percent to 0.07 percent Thorne (1986, 30
31 p. 145).

32 ⁶⁵ Derek Price de Solla (1984b, p. 54) notes that Galileo's discovery of the moons of Jupiter was the first 32
33 time in history that somebody made a discovery that had been totally unavailable to others by a process that 33
34 did not involve a deep and clever thought. 34

35 ⁶⁶ See Heilbron (1990, pp. 5–9). Interestingly, Heilbron believes that the main motives for these improve- 35
36 ments were *raisons d'état* and sheer curiosity, without allowing for the possibility that industrial and commer- 36
37 cial application might have contributed something. But in the same volume Lundgren (1990, p. 250) points 37
38 out that in Sweden the analytical quantification of assaying was a consequence of the expanding production 38
of minerals and ores.

39 ⁶⁷ The famous mathematician Pierre-Simon de Laplace was also a skilled designer of equipment and helped 39
40 to build the calorimeter that resulted in the celebrated "Memoir on Heat" jointly written by Laplace and 40
41 Lavoisier (in 1783), in which respiration was identified as analogous to burning. Much of the late eighteenth- 41
42 century chemical revolution was made possible by new instruments such as Volta's eudiometer, a glass 42
43 container with two electrodes intended to measure the content of air, used by Cavendish to show the nature of 43
water as a compound.

1 Volta's battery was soon produced in industrial quantities by William Cruickshank. 1
2 Through the new tool of electrolysis, pioneered by William Nicholson and Humphry 2
3 Davy, chemists were able to isolate element after element and fill in much of the detail 3
4 in the maps whose rough contours had been sketched by Lavoisier and Dalton. Volta's 4
5 pile, as Davy put it, acted as an "alarm bell to experimenters in every part of Europe" 5
6 [cited by Brock (1992, p. ??)]. The development of the technique of in vitro culture of 6
7 micro-organisms had similar effects (the Petri dish was invented in 1887 by R.J. Petri, 7
8 an assistant of Koch's). Price de Solla feels that many such advances in knowledge are 8
9 "adventitious" (1984a, p. 112). Travis (1989) has documented in detail the connection 9
10 between the tools developed in the organic chemical industry and advances in cell biol- 10
11 ogy. These connections between prescriptive and propositional knowledge are just a few 11
12 examples of advances in scientific techniques that can be seen as adaptations of ideas 12
13 originally meant to serve an entirely different purpose, and they reinforce the contingent 13
14 and accidental nature of much technological progress [Rosenberg (1994, pp. 251–252)]. 14

15 The invention of the modern compound microscope attributed to Joseph J. Lister (fa- 15
16 ther of the famous surgeon) in 1830 serves as another good example. Lister was an 16
17 amateur optician, whose revolutionary method of grinding lenses greatly improved im- 17
18 age resolution by eliminating spherical aberrations.⁶⁸ His invention and the work of 18
19 others changed microscopy from an amusing diversion to a serious scientific endeavor 19
20 and eventually allowed Pasteur, Koch, and their disciples to refute spontaneous genera- 20
21 tion and to establish the germ theory, a topic I return to below. The germ theory was one 21
22 of the most revolutionary changes in useful knowledge in human history and mapped 22
23 into a large number of new techniques in medicine, both preventive and clinical. Indeed, 23
24 the widespread use of glass in lenses and instruments in the West was itself something 24
25 coincidental, a "giant accident", possibly a by-product of demand for wine and different 25
26 construction technology [Macfarlane and Martin (2002)]. It seems plausible that with- 26
27 out access to this rather unique material, the development of propositional knowledge 27
28 in the West would have taken a different course.⁶⁹ 28

29 A third mechanism of technology feeding back into prescriptive knowledge is through 29
30 what might be called the "rhetoric of knowledge". This harks back to the idea of 30
31 "tightness" introduced earlier. Techniques are not "true" or "false". Either they work 31
32 according to certain predetermined criteria or they do not, and thus they can be interpreted 32
33 to confirm or refute the propositional knowledge that serves as their epistemic base. 33
34 Propositional knowledge has varying degrees of tightness, depending on the degree 34
35 to which the available evidence squares with the rhetorical conventions for accep- 35
36 tance. Laboratory technology transforms conjecture and hypothesis into an accepted 36
37 37

38 38
39 ⁶⁸ The invention was based on a mathematical optimization for combining lenses to minimize spherical aber- 39
40 ration and reduced average image distortion by a huge proportion, from 19 to 3 percent. Lister is reputed to 40
41 have been the first human being ever to see a red blood cell. 41

42 ⁶⁹ Macfarlane and Martin (2002, pp. 81–82) note that glass lenses not only made possible specific discoveries 42
43 but led to a growing confidence in a world of deeper truths to be discovered, destabilizing conventional views. 43
44 "The obvious was no longer true. Hidden connections and buried forces could be analyzed". 44

1 fact, ready to go into textbooks and to be utilized by engineers, physicians, or farmers. 1
2 But a piece of propositional knowledge in the past was often tested simply by verifying 2
3 that the techniques based on it actually worked. The earthenware manufacturer Josiah 3
4 Wedgwood felt that his experiments in pottery actually tested the theories of his friend 4
5 Joseph Priestley, and professional chemists, including Lavoisier, asked him for advice. 5
6 Similarly, once biologists discovered that insects could be the vectors of pathogenic mi- 6
7 croparasites, insect-fighting techniques gained wide acceptance. The success of these 7
8 techniques in eradicating yellow fever and malaria was the best confirmation of the hy- 8
9 potheses about the transmission mechanisms of the disease and helped earn them wide 9
10 support. 10

11 Or consider the question of heavier-than-air flight. Much of the knowledge in aero- 11
12 nautics in the early days was experimental rather than theoretical, such as attempts to 12
13 tabulate coefficients of lift and drag for each wing shape at each angle. It might be added 13
14 that the epistemic base supporting the first experiments of the Wright brothers was quite 14
15 untight: in 1901 the eminent astronomer and mathematician Simon Newcomb (the first 15
16 American since Benjamin Franklin to be elected to the Institute of France) opined that 16
17 flight carrying anything more than “an insect” would be impossible.⁷⁰ The success at 17
18 Kitty Hawk persuaded all but the most stubborn doubting Thomases that human flight in 18
19 heavier-than-air fixed wing machines was possible. Clearly their success subsequently 19
20 inspired a great deal of research on aerodynamics. In 1918 Ludwig Prandtl published his 20
21 magisterial work on how wings could be scientifically rather than empirically designed 21
22 and the lift and drag precisely calculated [Constant (1980, p. 105) and Vincenti (1990, 22
23 pp. 120–125)]. Even after Prandtl, not all advances in airplane design were neatly 23
24 derived from first principles in an epistemic base in aerodynamic theory, and the ancient 24
25 method of trial and error was still widely used in the search for the best use of flush 25
26 riveting in holding together the body of the plane or the best way to design landing gear 26
27 [Vincenti (1990, pp. 170–199; 2000)]. 27

28 It is important not to exaggerate the speed and abruptness of the transition. Thomas 28
29 Edison, a paradigmatic inventor of the 2nd Industrial Revolution, barely knew any sci- 29
30 ence, and in many ways should be regarded an old-fashioned inventor who invented 30
31 by trial-and-error through intuition, dexterity and luck. Yet he knew enough to know 31
32 what he did not know, and that there were others who knew what he needed. Among 32
33 those who supplied him with the propositional knowledge necessary for his research 33
34 were the mathematical physicist Francis Upton, the trained electrical engineer Hermann 34
35 Claudius, the inventor and engineer Nikola Tesla, the physicist Arthur E. Kennelly (later 35
36 professor of electrical engineering at Harvard), and the chemist Jonas W. Aylsworth. Yet 36
37 by that time access costs had declined enough so that he could learn for instance of the 37
38

39
40
41 ⁷⁰ He was joined in that verdict by the Navy’s chief engineer, Admiral George Melville [Kelly (1943, pp. 41
42 116–117) and Crouch (1989, p. 137)]. Nor were the inventors themselves all that certain: in a widely quoted 42
43 remark, Wilbur Wright in a despondent mood remarked to his brother that “not within a thousand years would 43
men ever fly” [Kelly (1943, p. 72)].

1 work of the great German physicist Hermann von Helmholtz through a translated copy 1
2 of the latter's work on acoustics. 2
3 The positive feedback from technology to prescriptive knowledge entered a new era 3
4 with development of the computer. In the past, the practical difficulty of solving differ- 4
5 ential equations limited the application of theoretical models to engineering. A clever 5
6 physicist, it has been said, is somebody who can rearrange the parameters of an insolu- 6
7 ble equation so that it does not have to be solved. Computer simulation can evade that 7
8 difficulty and help us see relations in the absence of exact closed-form solutions and may 8
9 represent the ultimate example of Bacon's "vexing" of nature. In recent years simula- 9
10 tion models have been extended to include the effects of chemical compounds on human 10
11 bodies. Combinatorial chemistry and molecular biology are both equally unimaginable 11
12 without fast computers. It is easy to see how the mutual reinforcement of computers and 12
13 their epistemic base can produce a virtuous circle that spirals uncontrollably away from 13
14 its basin of attraction. Such instability is the hallmark of Kuznets' vision of the role of 14
15 "useful knowledge" in economic growth. 15
16 In addition to the positive feedback within the two types of knowledge, one might 16
17 add the obvious observation that *access costs* were themselves a function of improving 17
18 techniques, through better communications, storage, and travel techniques. In this fash- 18
19 ion, expansions in prescriptive knowledge not only expanded the underlying supporting 19
20 knowledge but made it more accessible and thus more likely to be used. As already 20
21 noted, this is particularly important because so much technological progress consists of 21
22 combinations and applications of existing techniques in novel ways, or parallels from 22
23 other techniques in use. Precisely for this reason, cheap and reliable access to the mon- 23
24 ster catalog of all feasible techniques is an important element in technological progress. 24
25 As the total body of useful knowledge is expanding dramatically in our own time, it is 25
26 only with the help of increasingly sophisticated search engines that needles of useful 26
27 knowledge can be retrieved from a haystack of cosmic magnitude. 27
28 Technological modernity is created when the positive feedback from the two types 28
29 of knowledge becomes self-reinforcing and autocatalytic. We could think of this as a 29
30 phase transition in economic history, in which the old parameters no longer hold, and 30
31 in which the system's dynamics have been unalterably changed. There is no necessity 31
32 for this to be true even in the presence of positive feedback; but for certain levels of the 32
33 parameters, the system as a whole becomes unstable. It may well that this instability in 33
34 the knowledge-producing system are what is behind what we think of as "technological 34
35 modernity". Kuznets, of course, felt that the essence of modern growth was the in- 35
36 creasing reliance of technology on modern science. This view, as I have argued above, 36
37 needs clarification and amplification. Inside the black box of technology is a smaller 37
38 black box called "research and development" which translates inputs into the output of 38
39 knowledge. This black box itself contains an even smaller black box which models the 39
40 available knowledge in society, and it is this last box I have tried to pry open. Yet all 40
41 this is only part of the story: knowledge creates opportunities, but it does not guarantee 41
42 action. Knowledge is an abstract concept, it glosses over the human agents who possess 42
43 it and decide to act upon it. What motivates them, and why did some societies seem 43

1 to be so much more inclined to generate new knowledge and to exploit the knowledge 1
2 it had? To understand why during the past two centuries the “West” has been able to 2
3 take advantage of these opportunities we need to examine the institutional context of 3
4 innovation. 4

5 6 7 **7. Human capital and modern economic growth** 7 8

9 The role of education and human capital in the Industrial Revolution is more ambigu- 9
10 ous than much of the New Growth literature would suggest. Britain, the most advanced 10
11 industrial nation in 1850, was far from being the best educated, the most literate, or 11
12 in some other way the best-endowed in traditional human capital. Increases in male 12
13 literacy in Britain during the Industrial Revolution were in fact comparatively modest 13
14 and its educational system as a whole lagging behind [Mitch (1998)]. The Lutheran 14
15 nations of the Continent – Germany and the Scandinavian nations – were far more literate 15
16 and, in one formulation, “impoverished sophisticates”.⁷¹ Jewish minorities through- 16
17 out European history were unusually well-endowed in human capital [Botticini and 17
18 Eckstein (2003)], yet contributed little or nothing to the Industrial Revolution before 18
19 1850. Clearly human capital as a concept is indispensable, but we need to be far more 19
20 specific as to what *kind* of human capital was produced, for and by whom, what was 20
21 the source of the demand for it, and how it was distributed over the population. In his 21
22 recent survey, the social historian Peter Kirby (2003, p. 118) concludes that the idea that 22
23 nineteenth century education and literacy emerged as a response to a need for a trained 23
24 labor force is misleading. There was a significant gap between formal ‘education’ and 24
25 ‘occupational training’, the latter remaining embedded in the workplace in the form of 25
26 apprenticeships and trainee positions. Before 1870, at least, the rate of return on formal 26
27 education in his view was so low that its benefits did not outweigh the costs. That is not 27
28 to say that being literate did not convey advantages in terms of social and occupational 28
29 mobility [Long (2003)], but many of the skills that we associate with formal schooling 29
30 could be attained informally. 30

31 The historical role of human capital in economic growth in the past must then be re- 31
32 examined with some care. In terms of the framework delineated here its importance was 32
33 first in reducing access costs: literate and educated innovators could and did read arti- 33
34 cles, books and personal letters from scientists, as well as familiarize themselves with 34
35 techniques used elsewhere. They could understand mathematical and chemical notation, 35
36 interpret figures, read blueprints, and follow computations and mechanical arguments. 36
37 Moreover, by knowing more, the cost of *verification* fell: some obviously bogus and in- 37
38 effective pieces of propositional knowledge could be rejected offhand. Secondly, a more 38
39 literate and better educated labor force is assumed to be more competent, that is, be able 39
40 to execute instructions contained in more and more complex techniques. Yet because 40

41
42
43 ⁷¹ This is a term used by Lars Sandberg in a pathbreaking paper (1979). 41
42
43

1 the total set of useful knowledge could be divided up more and more thanks to better 1
2 access, the actual amount of such knowledge that a *single* worker had to control may not 2
3 have increased, it may have just changed, becoming more specialized, a smaller slice of 3
4 a bigger whole. Human capital may have been more important in learning *new* instruc- 4
5 tions, than in executing more complex and difficult techniques: as technology changed 5
6 more rapidly, technical tricks had to be learned and unlearned at more rapid rates. 6

7 Above all, investment in human capital is supposed to have created the conditions 7
8 for faster innovation. It made for the prepared minds that, as Pasteur famously said, are 8
9 favored by Fortune. Much technological progress consisted of fumbling and stumbling 9
10 into some lucky find – but only systematic training allowed inventors to recognize what 10
11 they found and how to apply it most fruitfully. Yet it is a fair question to ask of all 11
12 economists who draw links between demographic change and human capital on the one 12
13 hand and technological progress on the other – whether through the quality–quantity 13
14 trade-off or otherwise – how many inventors and technically competent people were 14
15 needed to generate sustained technological progress. 15

16 The answer, of course, depends, on what we mean by “competent”. Eighteenth cen- 16
17 tury Britain did have a cadre of highly skilled technicians and mechanics, almost all of 17
18 them trained in the apprenticeship system rather than in formal academies, and these 18
19 contributed materially to its technological development. The Continent, too, had its 19
20 share of skilled and well-trained craftsmen, although if we are to judge from the net 20
21 migration flow of talent, Britain may have had an edge, especially in coal-using in- 21
22 dustries.⁷² But the process of training apprentices did not always correspond to the 22
23 neoclassical depiction of human capital formation. In addition to imparting skills, it 23
24 was a selection process in which naturally gifted mechanics would teach themselves 24
25 from whatever source was available as much as learn from their masters. Such sources 25
26 multiplied as a direct result of the Industrial Enlightenment. In the eighteenth century 26
27 the publishing industry supplied a large flow of popular science books, encyclopedias, 27
28 technical dictionaries and similar “teach-yourself” kind of books.⁷³ These mechanics 28
29 and technicians were the ones that made the Industrial Revolution possible by generat- 29
30 ing a stream of microinventions that accounted for the actual productivity gains when 30
31 the great breakthroughs or macroinventions created the opportunities to do so and by 31
32 providing the competence to carry out the new instructions, that is, to build and con- 32
33 struct the new devices according to specifications.⁷⁴ 33
34 34
35 35

36 ⁷² Britain received as much as she gave in terms of skilled artisans and applied scientists: among the 36
37 foreigners who settled in Britain during the Industrial Revolution were the French inventor Aimé Argand, the 37
38 Portuguese applied scientists, instrument maker and merchant Jean-Hyacinthe de Magellan, the Italian phys- 38
39 icist Tiberius Cavallo, the German inventors Friedrich Koenig and Frederic Winsor (né Winzer), the Swiss 39
40 engineer J.G. Bodmer, and the great French engineer and machine builder, Marc I. Brunel. 40

41 ⁷³ Among the many eminent self-educated scientists was Michael Faraday, whose interests in electricity were 41
42 first stimulated by reading an article in the *Encyclopedia Britannica*. 42

43 ⁷⁴ An apt description of the importance of competence is provided by the early nineteenth-century steel in- 43
44 dustry: controlling the pace at which coal was fed to the furnace and its placing on the hearth [the skilled

1 How many such people were necessary? Better not teach the peasants how to read, 1
2 Voltaire reputedly said, someone has to plow the fields.⁷⁵ Technological change in the 2
3 era of the Industrial Revolution, based on invention, innovation, and implementation, 3
4 did not necessarily require that the entire labor force, or even most of it, much less the 4
5 population at large, be highly educated; that depended on whether the relation between 5
6 innovation and the growth of competence was strong and positive. An economy that 6
7 is growing technologically more sophisticated and more productive may end up using 7
8 techniques that are more difficult to invent and artefacts that are more complex in design 8
9 and construction, but may be easier to actually use and run on the shop floor. Production 9
10 techniques became more modular and standardized, meaning that labor might become 10
11 more specialized and that each worker had to know less rather than more. If much of the 11
12 new technology introduced after 1825 was like the self-actor – simpler to use if more 12
13 complex to build – it may well be that the best models to explain technological progress 13
14 (in the sense of inventing new techniques rather than implementing existing ones) foc- 14
15 us not on the *mean* level of human capital (or, as model-builders have it, the level of 15
16 human capital of a representative agent), but just on the *density in the upper tail* of the 16
17 distribution, that is, the level of education and sophistication of a small and pivotal elite 17
18 of engineers, mechanics, and chemists. Dexterous, motivated, well-trained technically, 18
19 and imaginative, with some understanding of the science involved, these workers turned 19
20 the ideas of the “Great Men” into production. The new technological system depended 20
21 on the increased skills of low-level technicians, supervisors, foremen, and skilled arti- 21
22 sans that the factories relied on to introduce new techniques on the shop floor and to 22
23 make the necessary adjustments to specific tasks and usages. What knowledge the firms 23
24 could not supply from its own workforce, it purchased from the outside in the form of 24
25 consulting engineers.⁷⁶ 25

26 Technical education for the masses might have been beneficial because among the 26
27 working classes there might have been “diamonds in the rough”, technically gifted 27
28

29
30 worker] had to cope with variations in the quality of the fuel and adjust his stoking accordingly and some- 29
31 times add coal of various sizes and grades . . . all this was a matter of judgement, but in many instances this 30
32 judgement governed the efficiency or even the practicability of the process. This sort of judgment was not the 31
33 kind of thing one learned from books” [Harris (1992a, p. 26)]. 32

33 ⁷⁵ This is the way Darnton (2003, p. 5) phrases it. Actually, Voltaire view was a bit more involved. In his 33
34 *Dictionnaire Philosophique* he noted that even in the most enlightened villages at most two peasants could read 34
35 and write, but that in no way affected their ability to build, plant and harvest. Adam Smith expressed the same 35
36 idea in his “Early Draft” for the *Wealth of Nations* when he noted that “to think or to reason comes to be, like 36
37 every other employment, a particular business, which is carried on by very few people who furnish the public 37
38 of the philosopher . . . may evidently descend to the meanest of people” if they led to improvements in the 38
39 mechanical arts [Smith (1978, pp. 569–572)]. 39

40 ⁷⁶ Such outside professional consultants included the famous British “coal-viewers” who advised coal mine 40
41 owners not only on the optimal location and structure of coal mines but also on the use of the Newcomen 41
42 steam pumps employed in mines in the eighteenth century [Pollard (1968, pp. 152–153)]. “Civil engineers” 42
43 was a term coined by the great engineer John Smeaton, who spent much of his life “consulting” to a large 43
number of customers in need of technical advice.

1 lads who, with the proper training, might have become part of the creative elite. The 1
2 sample of 316 industrialists assembled by [Crouzet \(1985\)](#) – admittedly only the tip 2
3 of a largely unknown pyramid – contained only 31 persons whose occupations were 3
4 “unskilled workmen” and only 16 fathers out of 226 “founders of large industrial un- 4
5 dertakings” were working class. The bulk of the labor force consisted of rank- and 5
6 file-workers whose ex post technical skills may have mattered but little, and thus any 6
7 model that relates human capital to demographic behavior runs into a serious dilemma. 7
8 Technological progress and competence had a complex relation because ingenuity and 8
9 detailed propositional knowledge could be frontloaded in the instructions or artefacts, 9
10 thus reducing the competence needed to carry out the actual production.⁷⁷ 10

11 It stands to reason that the ratio of competence to knowledge was higher in agricul- 11
12 ture than in manufacturing and in services, since a great deal of competence concerned 12
13 uncodified knowledge about very local and time-specific conditions of soil and weather. 13
14 As the share of agriculture in the labor force and total output declined, this may be 14
15 one reason why the relative importance of this form of human capital has declined in 15
16 the twentieth century. It has also been suggested [[Harris \(1992a\)](#)] that the importance 16
17 of tacit skills was especially prominent in coal-using industries such as glass and iron, 17
18 which explains Britain’s initial advantage in these industries and the need for Con- 18
19 tinental Europe to import British skilled workers during the years of “catching-up” 19
20 after 1800. 20

21 The human capital argument can be tested, at a rudimentary level, by looking at the 21
22 ratio between skilled and unskilled wages (or “wage premium”). The problem is of 22
23 course that without estimating a complete model of the market for skills, the historical 23
24 course of that ratio cannot be assigned to demand or supply factors. If, however, we 24
25 assume that technology is the prime mover in this market and we keep in mind that the 25
26 supply of skills will lag considerably behind a rise in wages (since the acquisition of 26
27 skills takes time), it would stand to reason that if the Industrial Revolution led to a net 27
28 increase in the demand for skilled labor, we should observe some increase in the skill 28
29 premium during the Industrial Revolution. No such change can be observed. Indeed, 29
30 recent research into the wage premium has established that it changed little between 30
31 1450 and 1900, yet it was much lower in Western Europe than in either Southern and 31
32 Eastern Europe or Asia, indicating perhaps that Europe was more capable in generat- 32
33 ing the kind of skills and abilities we associate with human capital in an age in which 33
34 literacy mattered less [[Van Zanden \(2004\)](#)]. It is even more surprising that in the twenti- 34
35 eth century this skill ratio declined precipitously [[Knowles and Robertson \(1951\)](#)]. This 35
36 36

37 37
38 38
39 ⁷⁷ An interesting example of such a technique is the construction of the *Nautical Almanacs*, detailed tables 39
40 that allowed sailors to calculate their longitude before Harrison’s clocks were cheap enough to be made 40
41 widely available, a technique pioneered by the German Astronomer Tobias Mayer in 1755. Nevil Maskelyne, 41
42 the Astronomer Royal, designed tables put together by highly numerate “computers” that would allow seamen 42
43 to compute with accuracy their location at sea in 30 minutes instead of the four hours required by Mayer’s 43
44 original technique [[Croarken \(2002\)](#)]. 44

1 could be caused by an (otherwise unexplained) increase in supply, but it is at least con- 1
2 sistent with a story that stresses the ability of unskilled labor to operate effectively in a 2
3 sophisticated technology environment. 3

4 The argument I propose, that technological progress is driven by a relatively small 4
5 number of pivotal people, is not a call for a return to the long-defunct “heroic inven- 5
6 tor” interpretation of the Industrial Revolution. The great British inventors stood on the 6
7 shoulders of those who provided them with the wherewithal of tools and workmanship. 7
8 John Wilkinson, it is often remarked, was indispensable for the success of James Watt, 8
9 because his Bradley works had the skilled workers and equipment to bore the cylin- 9
10 ders exactly according to specification. Mechanics and instrument makers such as Jesse 10
11 Ramsden, Edward Nairn, Joseph Bramah, and Henry Maudslay; clock-makers such as 11
12 Henry Hindley, Benjamin Huntsman (the inventor of the crucible technique in making 12
13 high-quality steel), John Whitehurst (a member of the Lunar Society), and John Kay of 13
14 Warrington (not to be confused with his namesake, the inventor of the flying shuttle, 14
15 who was trained as a reed- and comb-maker), engineers such as John Smeaton, Richard 15
16 Roberts, and Marc I. Brunel; ironmasters such as the Darbys, the Crowleys, and the 16
17 Crawshays; steam engine specialists such as William Murdoch and Richard Trevithick; 17
18 chemists such as John Roebuck, Alexander Chisholm, and James Keir were as much 18
19 part of the story as the “textbook superstars” Arkwright, Cort, Crompton, Hargreaves, 19
20 Cartwright, Trevithick, and Watt.⁷⁸ These were obviously men who could squeeze a 20
21 great deal out of a narrow epistemic base and who could recognize more effective useful 21
22 knowledge and base better techniques on them. Eventually, however, there was no es- 22
23 caping a more formal and analytical approach, in which a widening reliance on physics 23
24 and mathematics was inevitable. Oddly enough, this approach originated in France more 24
25 than in Britain.⁷⁹ Over the nineteenth century, the importance of advantages in compe- 25
26 tence (tacit skills and dexterity) declined, and that of formal codified useful knowledge 26
27 increased, eroding the advantages Britain may have had through its skilled craftsmen 27
28 that other nations envied and coveted in the years before 1815. 28

29 Below the great engineers came a much larger contingent of skilled artisans and 29
30 mechanics, upon whose dexterity and adroitness the top inventors and thus Britain’s 30
31 technological success relied. These were the craftsmen, highly skilled clock- and 31
32 instrument-makers, woodworkers, toymakers, glasscutters, and similar specialists, 32
33 who could accurately produce the parts, using the correct dimensions and materials, 33
34 who could read blueprints and compute velocities, understood tolerance, resistance, 34
35 friction, and the interdependence of mechanical parts. These were the applied chemists 35
36 36

37 37
38 ⁷⁸ A good description of this class of people is provided by Griffiths’ judgment of William Murdoch (the 38
39 gifted and ingenious Watt and Boulton employee, credited with the invention of the famous Sun-and-Planets 39
40 gear): “his inventiveness was instinctive, not analytical. He had an innate sense of mechanical propriety, of 40
41 the chose juste, which led him to simple, robust and highly original solutions” [Griffiths (1992, p. 209)]. 41

42 ⁷⁹ The “Big Three *polytechnicien*” engineers of the early nineteenth century, Gustave-Gaspard Coriolis, Jean- 42
43 Victor Poncelet, and Louis Navier, placed mechanical and civil engineering on a formal base, and supported 43
practical ideas with more mathematical analysis than their more pragmatic British colleagues.

1 who could manipulate laboratory equipment and acids, the doctors whose advice some- 1
2 times saved lives even if nobody quite yet understood why, agricultural specialists who 2
3 experimented with new breeds of animals, fertilizers, drainage systems, and fodder 3
4 crops. These anonymous but capable workers produced a cumulative torrent of small, 4
5 incremental, but cumulatively indispensable micro inventions without which Britain 5
6 would not have become the “workshop of the world”. They were artisans, but they were 6
7 the skilled aristocracy of the trained craftsmen, not the average man in his workshop. 7
8 It is perhaps premature to speak of an “invention industry” by this period, but technical 8
9 knowledge at a level beyond the reach of the run-of-the-mill artisan became increasingly 9
10 essential to create the inventions associated with the Industrial Revolution. 10

11 The average “quality” of the majority of the labor force – in terms of their technical 11
12 training – may thus be less relevant to the development and adoption of the new tech- 12
13 niques less than is commonly believed. The distribution of knowledge within society 13
14 was highly skewed, but as long as access costs were sufficiently low, such a skewedness 14
15 would not impede further technological progress. Rosenberg has pointed out that in 15
16 Adam Smith’s view the *modal* level of knowledge may be low, the highest levels of 16
17 scientific attainment were remarkable and the *collective* intelligence of a civilized soci- 17
18 ety is great and presents unprecedented opportunities for further technological progress 18
19 [Rosenberg (1965, p. 137)]. A venerable tradition in economic history, in fact, has ar- 19
20 gued that technological progress in the first stages of the Industrial Revolution was 20
21 “deskilling”, requiring workers who were able to carry out repetitive routine actions 21
22 instead of the skilled labor of skilled craftsmen.⁸⁰ The “factory system” required work- 22
23 ers to be supervised and assisted by skilled mechanics, and hence the variance of the 23
24 skill level may have increased even if we cannot be sure whether *average* skills had to 24
25 go up or down. Much innovation, both historically and in our time, has been deliber- 25
26 ately aimed to be *competence-reducing*, that is made more user-friendly and requiring 26
27 less skill and experience to use even if it took far more knowledge to design.⁸¹ Human 27
28 capital was instrumental in creating competence rather than useful knowledge itself, in 28
29 teaching how to carry out instructions rather than writing them. Yet given that much 29
30 of what I termed above competence consisted of tacit knowledge and experience, and 30
31 given that much of the competence could be front-loaded into the equipment by a small 31
32 number of brilliant designers, the role of either the size of the population or their “mean” 32
33 33

34 34
35 35
36 ⁸⁰ Deskilling probably commenced already in the century before the Industrial Revolution, when much of the 36
37 manufacturing in Europe was carried out in the homes of unskilled rural workers. Yet the cottage industries of 37
38 Europe were certainly capable of technological change even if their limited size in the end imposed a binding 38
39 constraint. See especially Berg (1994). 39

40 ⁸¹ An earlier example of such competence-reducing innovation was the introduction of fire-arms in Europe 40
41 in the fifteenth century. Early fire-arms were not as effective as the longbow, but the latter took an inordinate 41
42 amount of skill and strength to operate, whereas the use of fire-arms could be taught in a few weeks. In 42
43 that regard, there is an interesting parallel between the “military revolution” of the fifteenth century and the 43
Industrial Revolution.

1 level of human capital should be questioned. It seems plausible that the degree of net- 1
2 working and the level of access costs *within* the relatively small community of highly 2
3 trained engineers and scientists may have been of greater importance. 3

4 Furthermore, the term “skill” may be too confining. Human capital was in part pro- 4
5 duced in schools, but what future workers were taught in schools may have had as much 5
6 to do with behavior as with competence. Docility and punctuality were important char- 6
7 acteristics that factory owners expected from their workers. “The concept of industrial 7
8 discipline was new, and called for as much innovation as the technical inventions of the 8
9 age”, writes Pollard (1968 [1965], p. 217). Early factories designed incentives to bring 9
10 about the discipline, but they also preferred to hire women and children, who were be- 10
11 lieved to be more docile. Skill may have mattered less than drill. Some of the literature 11
12 by economists on human capital acquisition may have to be reinterpreted in this fashion. 12
13

14 8. Institutions and technological progress 15

16 Beyond the interaction of different kinds of knowledge was the further level of inter- 16
17 action and feedback between human knowledge and the institutional environment in 17
18 which it operates. Before 1750, economic progress of any kind had tended to run into 18
19 what could best be called negative institutional feedback. One of the few reliable regu- 19
20 larities of the pre-modern world was that whenever a society managed, through thrift, 20
21 enterprise, or ingenuity to raise its standard of living, a variety of opportunistic parasites 21
22 and predators were always ready to use power, influence, and violence to appropriate 22
23 this wealth. Such rent-seekers, who redistributed wealth rather than created it, came ei- 23
24 ther from within the economy in the form of tax-collectors, exclusive coalitions, and 24
25 thugs, or they came from outside as alien pillagers, mercenaries, and plunderers. The 25
26 most obvious and costly form of negative institutional feedback before 1815 was, of 26
27 course, war. Rent-seeking and war often went in hand-in-hand. Britain, France, the 27
28 United Provinces and most other Continental powers fought one another constantly in 28
29 hugely costly attempts to redistribute taxable real estate, citizens and activities from one 29
30 to the other, a typical “mercantilist” kind of policy.⁸² Economic growth indirectly helped 30
31 instigate these conflicts. Wealth accumulation, precisely because it was mostly the re- 31
32 sult of “Smithian Growth”, was usually confined to a region or city and thus created an 32
33 incentive to greedy and well-armed neighbors to engage in armed rent-seeking. It surely 33
34 is no accident that the only areas that had been able to thwart off such marauders with 34
35 some success were those with natural defenses such as Britain and the Netherlands. Yet 35
36 the Dutch United Provinces were weakened by the relentless aggressive mercantilist 36
37 37
38 38

39 39
40 40
41 ⁸² O’Brien (2003, p. 5) notes that between the Nine-Years War (starting in 1688) and the Congress of Vienna 41
42 in 1815, Britain and France were at or on the brink of war for more than half the period, justifying the term 42
43 “Second Hundred-Years War”. 43

1 policies of powerful neighbors.⁸³ The riches of the Southern Netherlands – unfortu- 1
2 nately easier to invade – were repeatedly laid to waste by invading mercenary soldiers 2
3 after 1570. More subtle forms of rent-seeking came from local monopolists (whose 3
4 claims to a right to exclude others were often purchased from strongmen), guilds with 4
5 exclusionary rights, or nobles with traditional rights such as *banalités*. A particularly 5
6 harmful form of rent-seeking were price controls on grain that redistributed resources 6
7 from the countryside to the city by keeping grain prices at below equilibrium levels 7
8 [Root (1994)]. 8

9 Had institutional feedback remained negative, as it had been before 1750, the eco- 9
10 nomic benefits of technological progress would have remained limited. Mercantilism, 10
11 as Ekelund and Tollison (1981, 1997) have emphasized, was largely a system of rent 11
12 seeking, in which powerful political institutions redistributed wealth from foreigners 12
13 to themselves as well between different groups and individuals within the society. The 13
14 political economy associated with the Enlightenment increasingly viewed the old rent- 14
15 seeking traditions of exclusionary privileges as both unfair and inefficient. Mercantilism 15
16 had been a game of international competition between rival political entities. To defeat 16
17 an opponent, a nation had to outcompete it, which it often did by subsidizing exports and 17
18 raw materials imports, and imposing a tariff on finished goods. As it dawned upon peo- 18
19 ple that higher productivity could equally outcompete other producers, they switched 19
20 to a different policy regime, one that economists certainly would recognize as more 20
21 enlightened.⁸⁴ In the decades around 1750, mercantilism had begun to decline in cer- 21
22 tain key regions in Western Europe, above all in Britain, where many redistributive 22
23 arrangements such as guilds, monopolies, and grain price regulations were gradually 23
24 weakening, though their formal disappearance was still largely in the future. The Age 24
25 of Enlightenment led to some pre-1789 reforms on the Continent thanks to a few en- 25
26 lightened despots, but it was the French Revolution and the ensuing political turmoil that 26
27 did more than anything else to transform Enlightenment ideas into genuine institutional 27
28 changes that paved the road for economic growth. The Enlightenment also advocated 28
29 more harmonious and cosmopolitan attitudes in international relations and its influence 29
30 may have contributed to the relative calm that settled upon Europe after the Congress of 30
31 Vienna. Political reforms that weakened privileges and permitted the emergence of freer 31
32 and more competitive markets had an important effect on economic performance. The 32
33

34
35 ⁸³ The standard argument is that national defense was so costly that high indirect taxes led to high nominal 35
36 wages, which rendered much of Dutch manufacturing uncompetitive. See for example Charles Wilson (1969). 36
37 De Vries and Van Der Woude (1997, p. 680) point out that in 1688 the Dutch committed huge resources to 37
38 an invasion of England because the future economic well-being on the Republic depended on the destruction 38
39 of French mercantilism and the establishment of an international order in which the Dutch economy could 39
40 prosper, yet it “proved to be a profitless investment”. More recently, Ormrod (2003) has confirmed the view 40
41 that the decline of the Dutch Republic was a direct consequence of the mercantilist policies of its neighbors, 41
42 especially Britain. 42

43 ⁸⁴ In 1773, the steam engine manufacturer Matthew Boulton told Lord Harwich that mechanization and 43
44 specialization made it possible for Birmingham manufacturers to defeat their Continental competitors [cited 44
45 by Uglow (2002, p. 212)]. 45

1 institutional changes in the years between 1770 and 1815 saw to it that the Industrial 1
2 Revolution was not followed by a surge in rent-seeking and violence that eventually 2
3 could have reversed the process [Mokyr (2003b)]. 3

4 The positive feedback between technological and institutional change is central to 4
5 the process of historical change. The co-evolution of technological knowledge and in- 5
6 stitutions during the second Industrial Revolution has been noticed before.⁸⁵ Above 6
7 all, three kind of institutions were important in facilitating the sustained technological 7
8 progress central to economic growth: (1) those that provided for connections between 8
9 the people concerned mostly with propositional knowledge and those on the production 9
10 side; (2) those that set the agenda of research to generate new propositional knowledge 10
11 that could be mapped into new techniques; and (3) those institutions that created and 11
12 safeguarded *incentives* for innovative people to actually spend efforts and resources in 12
13 order to map this knowledge into techniques and specifically that weakened the effec- 13
14 tive social and political resistance against new techniques. As noted above, even some 14
15 of the formal endogenous growth models require a growing proportion of labor in the 15
16 “invention sector”, a condition that clearly demands that their profits not be expropriated 16
17 altogether. 17

18 The formal institutions that created the bridges between prescriptive and proposi- 18
19 tional knowledge in late eighteenth and nineteenth century Europe are well understood: 19
20 scientific societies, universities, polytechnic schools, publicly funded research insti- 20
21 tutes, museums, agricultural research stations, research departments in large financial 21
22 institutions. Improved access to useful knowledge took many forms. Cheap and widely 22
23 diffused publications disseminated it. All over the Western world, textbooks of applied 23
24 science (or “experimental philosophy” in the odd terminology of the time), professional 24
25 journals, technical encyclopedias, and engineering manuals appeared in every field and 25
26 made it easier to “look things up”. Technical subjects penetrated school curricula in 26
27 every country in the West (although Britain, the leader in the first Industrial Revolution, 27
28 lost its momentum in the Victorian era). The professionalization of expertise meant in- 28
29 creasingly that anyone who needed some piece of useful knowledge could find someone 29
30 who knew, or who knew someone who knew. Learned technical journals first appeared 30
31 in the 1660s and by the late eighteenth century had become one of the main vehicles by 31
32 which prescriptive knowledge was diffused. In the eighteenth century, most scientific 32
33 journals were in fact deliberately written in an accessible style, because they more often 33
34 34

35 35

41 41
42 42
43 43

⁸⁵ Nelson (1994) has pointed to a classic example, namely the growth of the large American business corporation in the closing decades of the nineteenth century, which evolved jointly with the high-throughput technology of mass production and continuous flow. In their pathbreaking book, Fox and Guagnini (1999) have pointed to the growth of practically-minded research laboratories in academic communities, which increasingly cooperated and interacted successfully with industrial establishments to create an ever-growing stream of technological adaptations and microinventions. Many other examples can be cited, such as the miraculous expansion of the British capital market which emerged jointly with the capital-hungry early railroads and the changes in municipal management resulting from the growing realization of the impact of sanitation on public health [Cain and Elyce (2001)].

1 than not catered to a lay audience and thus were media of education and dissemination
2 rather than repositories of original contributions [Kronick (1962, p. 104)]. Review
3 articles and book reviews that summarized and abstracted books and learned papers (es-
4 specially those published overseas and were less accessible), another obvious example of
5 an access-cost reduction, were popular.⁸⁶ In the nineteenth century, specialized scienti-
6 fic journals became increasingly common and further reduced access costs, if perhaps
7 more and more requiring the intermediation of experts who could decode the jargon.

8 To be sure, co-evolution did not always quickly produce the desired results. The
9 British engineering profession found it difficult to train engineers using best-practice
10 knowledge, and the connections between science and engineering remained looser and
11 weaker than elsewhere. In 1870 a panel appointed by the Institute of Civil Engineers
12 concluded that “the education of an Engineer [in Britain] is effected by ... a simple
13 course of apprenticeship to a practicing engineer ... it is not the custom in England
14 to consider *theoretical* knowledge as absolutely essential” [cited by Buchanan (1985,
15 p. 225)]. A few individuals, above all William Rankine at Glasgow, argued forcefully for
16 more bridges between theory and practice, but significantly he dropped his membership
17 in the Institute of Civil Engineers. Only in the late nineteenth century did engineering
18 become a respected discipline in British universities.

19 Elsewhere in Europe, the emergence of universities and technical colleges that com-
20 bined research and teaching advanced rapidly, thus simultaneously expanding proposi-
21 tional knowledge and reducing access costs. An especially good and persuasive example
22 is provided by Murmann (2003), who describes the co-evolution of technology and in-
23 stitutions in the chemical industry in imperial Germany, where the new technology of
24 dyes, explosives, and fertilizers emerged in constant interaction with the growth of re-
25 search and development facilities, institutes of higher education, and large industrial
26 corporations with a knack for industrial research.⁸⁷ Institutions remained a major deter-
27 minant of access costs. To understand the evolution of knowledge, we need to ask who
28 talked to whom and who read what. Yet the German example illustrates that progress in
29 this area was halting and complex; it needs to be treated with caution as a causal factor in
30 explaining systematic differences between nations. The famed *technische Hochschulen*,
31 in some ways the German equivalent of the French *polytechniques*, had lower social
32 prestige than the universities and were not allowed to award engineering diplomas
33 and doctorates till 1899. The same is true for the practical, technically oriented *Re-
34 alschulen*, which had lower standing than the more classically inclined *Gymnasien*.
35 Universities conducted a great deal of research, but it goes too far to state that what
36
37

38 ⁸⁶ This aspect of the Industrial Enlightenment was personified by the Scottish writer and mathematician John
39 Playfair (1748–1819) whose textbooks and review essays in the *Edinburgh Review* made a special effort
40 to incorporate the work of Continental mathematicians, as witnessed by the essays in 1807 on the work of
41 Mechain and Delambre on the Earth’s meridian, and his 1808 review of Laplace’s *Traité de Mécanique Celeste*
42 [Chitnis (1976, pp. 176–177, 222)].

43 ⁸⁷ Most famous, perhaps, was the invention of alizarin in 1869, a result of the collaboration between the
44 research director at BASF, Caro, with the two academics Graebe and Liebermann.

1 they did was a *deliberate* application of science to business problems.⁸⁸ Universities 1
2 and businesses co-evolved, collaborating through personal communications, overlap- 2
3 ping personnel, and revolving doors. The second Industrial Revolution rested as much 3
4 on industry-based science as on the more common concept of science-based industry 4
5 [König (1996)]. 5

6 Designing institutions that create the correct *ex ante* motivations to encourage inven- 6
7 tion is not an easy task. Economists believe that agents respond to economic incentives. 7
8 A system of relatively secure property rights, such as emerged in Britain in the seven- 8
9 teenth century, is widely regarded as a prerequisite. Without it, even if useful knowledge 9
10 would expand, the investment and entrepreneurship required for a large scale implemen- 10
11 tation of the new knowledge would not have been forthcoming. On a more specific level, 11
12 the question of the role of intellectual property rights and rewards for those who add to 12
13 the stock of useful knowledge in generating economic growth is paramount. Some of the 13
14 best recent work in the economic history of technological change focuses on the work- 14
15 ing of the patent system as a way of preserving property rights for inventors. In a series 15
16 of ingenious papers, Kenneth Sokoloff and Zorina Khan have shown how the Ameri- 16
17 can patent system exhibited many of the characteristics of a market system: inventors 17
18 responded to demand conditions, did all they could to secure the gains from their in- 18
19 vention and bought and sold licenses in what appears to be a rational fashion. It was far 19
20 more accessible, open, and cheaper to use than the British system, and attracted ordi- 20
21 nary artisans and farmer as much as it did professional inventors and eccentrics [Khan 21
22 and Kenneth (1993, 1998, 2001) and Khan (2002)]. 22

23 Whether this difference demonstrates that a well-functioning system of intellectual 23
24 property rights was essential to the growth of useful knowledge remains an open ques- 24
25 tion. For one thing, the American system was far more user-friendly than the British 25
26 patent system prior to its reform in 1852. Yet despite the obvious superiority of the U.S. 26
27 system and the consequent higher propensity of Americans to patent, there can be little 27
28 doubt that the period between 1791 and 1850 coincides roughly with the apex of British 28
29 superiority in invention. The period of growing American technological leadership, af- 29
30 ter 1900, witnessed a stagnation and then a decline in the American per capita patenting 30
31 rate. Other means of appropriating the returns on R&D became relatively more attrac- 31
32 tive. In Britain, MacLeod (1988) has shown that the patent system during the Industrial 32
33 Revolution provided only weak and erratic protection to inventors and that large areas 33
34 of innovation were not patentable. Patenting was associated with commercialization and 34
35 35

36 36
37 37
38 ⁸⁸ James (1990, p. 111) argues that Germany's "staggering supremacy" was not due to scientists looking for 38
39 applicable results but came about "because her scientists experimented widely without any end in mind and 39
40 then discovered that they could apply their new information". This seems a little overstated, but all the same 40
41 we should be cautious in attributing too much intent and directionality in the growth of knowledge. Much of 41
42 it was in part random or the unintended consequence of a different activity, and it was the selection process 42
43 that gave it its technological significance. In that respect, the evolutionary nature of the growth in useful 43
knowledge is reaffirmed.

1 the rise of a profit-oriented spirit, but its exact relation to technological progress is still 1
2 obscure.⁸⁹ 2

3 What is sometimes overlooked is that patents placed technical information in the 3
4 public realm and thus reduced access costs. Inventors, by observing what had been done, 4
5 saw what was possible and were inspired to apply the knowledge thus acquired to other 5
6 areas not covered by the patent. In the United States, *Scientific American* published lists 6
7 of new patents from 1845, and these lists were widely consulted. Despite the limitations 7
8 that patents imposed on applications, these lists reduced access costs to the knowledge 8
9 embodied in them. The full specification of patents was meant to inform the public. 9
10 In Britain this was laid out in a decision by chief justice Lord Mansfield, who decreed 10
11 in 1778 that the specifications should be sufficiently precise and detailed so as to fully 11
12 explain it to a technically educated person. In the Netherlands, where patenting had 12
13 existed from the 1580s, the practice of specification was abandoned in the mid-1630s 13
14 but revived in the 1770s [Davids (2000, p. 267)]. 14

15 In at least two countries, the Netherlands and Switzerland, the complete absence of a 15
16 patent system in the second half of the nineteenth century does not seem to have affected 16
17 the rate of technological advance [Schiff (1971)]. Of course, being small, such countries 17
18 could and did free-ride on technological advances made elsewhere, and it would be a 18
19 fallacy to infer from the Dutch and Swiss experience that patents did not matter. It 19
20 also seems plausible that reverse causation explains part of what association there was 20
21 between the propensity to patent and the generation of new techniques: countries in 21
22 which there were strong and accessible bridges between the *savants* and the *fabricants* 22
23 would feel relatively more need to protect the offspring of these contacts. Lerner (2000) 23
24 has shown that rich and democratic economies, on the whole, provided more extensive 24
25 patent protection. The causal chain could thus run from technological success to income 25
26 and from there to institutional change rather than from the institutions to technological 26
27 success, as Khan and Sokoloff believe. It may well be true, as Abraham Lincoln said, 27
28 that what the patent system did was “to add the fuel of interest to the fire of genius” 28
29 [cited by Khan and Kenneth (2001, p. 12)], but that reinforces the idea that we need to 29
30 be able to say something about how the fire got started in the first place. 30

31 Other institutions have been widely recognized as aiding in the generation of new 31
32 techniques. Among those are relatively easy entry and exit from industries, the avail- 32
33 ability of venture capital in some form, the reduction of uncertainty by a large source 33
34 of assured demand for a new product or technique (such as military procurement or 34
35 35

36 36
37 ⁸⁹ In fact, economists have argued that for countries that are technologically relatively backward, strict patent 37
38 systems may be on balance detrimental to economic welfare [for a summary, see Lerner (2000)]. In a different 38
39 context, Hilaire-Pérez (2000) has shown how different systems of invention encouragement in eighteenth- 39
40 century Europe were consistent with inventive activity: whereas in France the state played an active role of 40
41 awarding “privileges” and pensions to inventors deemed worthy by the French Academy, in Britain the state 41
42 was more passive and allowed the market to determine the rewards of a successful inventor. These systems 42
43 were not consistently enforced (some British inventors whose patents for one reason or another failed to pay 43
44 off were compensated by special dispensation) and, as Hilaire-Pérez shows, influenced one another.

1 captive colonial markets), the existence of agencies that coordinated and standardized 1
2 the networked components of new techniques, and revolving doors between industry 2
3 and organizations that specialize in the generation of propositional knowledge such as 3
4 universities and research institutes. 4

5 There is a fundamental complementarity between knowledge growth and institu- 5
6 tional change in the economic growth of the West. Augmenting and diffusing knowl- 6
7 edge produced the seeds that germinated in the fertile soils that economic incentives 7
8 and functional markets created. Without the seeds, improved incentives for innovation 8
9 would have been useless. Commercial, entrepreneurial, and even sophisticated capital- 9
10 ist societies have existed that made few important technical advances, simply because 10
11 the techniques they employed rested on narrow epistemic bases and the propositional 11
12 knowledge from which these bases were drawn was not expanding. The reasons for this 12
13 could be many: the agendas of intellectual activity may not have placed a high prior- 13
14 ity on *useful* knowledge, or a dominant conservative religious philosophy might have 14
15 stifled a critical attitude toward existing propositional knowledge. Above all, there has 15
16 to be a belief that such knowledge may eventually be socially useful even if the gains 16
17 are likely to be reaped mostly by persons others than the ones who generate the novel 17
18 propositional knowledge. Given that increasing this knowledge was costly and often 18
19 regarded as socially disruptive, the political will by agents who controlled resources to 19
20 support this endeavor, whether they were rich aristocratic patrons or middle-class tax- 20
21 payers, was not invariably there. The amounts of resources expended on R&D, however, 21
22 are not more important than questions about how they were spent, on what, and what 22
23 kind of access potential users had to this knowledge. 23

24 One specific example of an area in which technological innovation and institutional 24
25 change interacted in this fashion was in the resistance of vested interests to new tech- 25
26 nology [Mokyr (1994, 2002)]. Here institutions are particularly important, because by 26
27 definitions such resistance has to operate outside the market mechanism. If left to mar- 27
28 kets to decide, it seems likely that superior techniques and products will inexorably 28
29 drive out existing ones. For the technological status quo to fight back thus meant to use 29
30 non-market mechanisms. These could be legal, through the manipulation of the existing 30
31 power structure, or extralegal, through machine-breaking, riots, and the use of personal 31
32 violence against inventors and the entrepreneurs who tried to adopt their inventions. 32

33 At one level, eighteenth-century Enlightenment thinking viewed technological 33
34 change as “progress” and implicitly felt that social resistance to it was socially unde- 34
35 sirable. Yet there was a contrary strand of thought, associated with Rousseau and with 35
36 later elements of romanticism such as Cobbett and Carlyle continuing with the Frank- 36
37 furt school in the twentieth century, that sincerely viewed industrialization and modern 37
38 technology and the enlightenment that spawned them as evil and destructive. Such ide- 38
39 ological qualms often found themselves allied with those whose human and physical 39
40 capital was jeopardized by new techniques. Mercantilist thought, with its underlying as- 40
41 sumptions of a zero-sum society, was hugely concerned with the employment-reducing 41
42 effects of technological progress. The ensuing conflict came to a crashing crescendo 42
43 during the Industrial Revolution. The Luddite rebellion – a complex set of events that 43

1 involved a variety of grievances, not all of which were related to rent-seeking – was mer- 1
2 cilessly suppressed. It would be a stretch to associate the harsh actions of the British 2
3 army in the midlands in 1812 with anything like the Enlightenment. All the same, it 3
4 appears that rent-seeking inspired resistance against new technology had been driven 4
5 into a corner by that time by people who believed that “freedom” included the freedom 5
6 to innovate and that higher labor productivity did not necessarily entail unemployment. 6

7 The British example is quite telling.⁹⁰ In the textile industries, by far the most re- 7
8 sistance occurred in the woolen industries. Cotton was a relatively small industry on 8
9 the eve of the Industrial Revolution and had weakly entrenched power groups. There 9
10 were riots in Lancashire in 1779 and 1792, and a Manchester firm that pioneered a 10
11 powerloom was burnt down. Yet cotton was unstoppable and must have seemed that 11
12 way to contemporaries. Wool, however, was initially far larger and had an ancient tra- 12
13 dition of professional organization and regulation. Laborers in the wool trades tried to 13
14 use the political establishment for the purposes of stopping the new machines. In 1776 14
15 workers petitioned the House of Commons to suppress the jennies that threatened the 15
16 livelihood of the industrious poor, as they put it. After 1789, Parliament passed sets of 16
17 repressive laws (most famously the Combination Act of 1799), which in [Horn’s \(2003\)](#) 17
18 view were not only intended to save the regime from French-inspired revolutionary 18
19 turmoil, but also to protect the Industrial Revolution from resistance “from below”. 19
20 Time and again, groups and lobbies turned to Parliament requesting the enforcement of 20
21 old regulations or the introduction of new legislation that would hinder the machinery. 21
22 Parliament refused. The old laws regulating the employment practices in the woolen in- 22
23 dustry were repealed in 1809, and the 250 year old Statute of Artificers was repealed in 23
24 1814. Lacking political support in London, the woolworkers tried extralegal means. As 24
25 [Randall](#) has shown, in the West of England the new machines were met in most places 25
26 by violent crowds, protesting against jennies, flying shuttles, gig mills, and scribbling 26
27 machines [[Randall \(1986, 1989\)](#)]. Moreover, in these areas magistrates were persuaded 27
28 by fear or propaganda that the machine breakers were in the right. The tradition of vi- 28
29 olence in the West of England, writes [Randall](#), deterred all but the most determined 29
30 innovators. Worker resistance was responsible for the slow growth and depression of 30
31 the industry rather than the reverse [[Randall \(1989\)](#)]. The West of England, as a result, 31
32 lost its supremacy to Yorkshire. Resistance in Yorkshire was not negligible either, but 32
33 there it was unable to stop mechanization. Violent protests, such as the Luddite riots, 33
34 were forcefully suppressed by soldiers. As [Paul Mantoux](#) put it well many years ago, 34
35 “Whether [the] resistance was instinctive or considered, peaceful or violent, it obviously 35
36 had no chance of success” [[Mantoux \(1961 \[1928\], p. 408\)](#)]. Had that not been the case, 36
37 sustained progress in Britain would have been severely hampered and possibly brought 37
38 to an end.⁹¹ 38
39 39
40 40

41 ⁹⁰ Some of the following is based on [Mokyr \(1994\)](#). 41

42 ⁹¹ As [Randall](#) has shown, in the West of England the new machines were met by violent crowds, protesting 42
43 against jennies, flying shuttles, gig mills, and scribbling machines [[Randall \(1986, 1989\)](#)]. Moreover, in these 43

1 In other industries, too, resistance appeared, sometimes from unexpected corners. 1
2 When Samuel Clegg and Frederick Windsor proposed a central gas distribution plan for 2
3 London, they were attacked by a coalition that included the eminent scientist Humphry 3
4 Davy, the novelist Walter Scott, the cartoonist George Cruickshank, insurance compa- 4
5 nies, and the aging James Watt [Stern (1937)]. The steam engine was resisted in urban 5
6 areas by fear of “smoky nuisances”, and resistance to railroads was rampant in the first 6
7 years of their incipience. Mechanical sawmills, widely used on the Continent, were vir- 7
8 tually absent from Britain until the nineteenth century.⁹² Even in medical technology, 8
9 where the social benefits were most widely diffused, the status quo tried to resist. When 9
10 Edward Jenner applied to the Royal Society to present his findings, he was told “not 10
11 to risk his reputation by presenting to this learned body anything which appeared so 11
12 much at variance with established knowledge and withal so incredible” [Keele (1961, 12
13 p. 94)].⁹³ In medical technology, in general, resistance tended to be particularly fierce 13
14 because many of the breakthroughs after 1750 were inconsistent with accepted doc- 14
15 trine, and rendered everything that medical professionals had laboriously learned null 15
16 and void. It also tended, more than most other techniques, to incur the wrath of ethical 16
17 purists who felt that some techniques in some way contradicted religious principles, not 17
18 unlike the resistance to cloning and stem-cell research in our own time. Even such a 18
19 seemingly enormously beneficial and harmless invention as anesthesia was objected on 19
20 a host of philosophical grounds [Youngson (1979, pp. 95–105; 190–198)]. 20

21 With the rise in the factory and the strengthening of the bargaining power of capi- 21
22 talists, authority and discipline might have reduced, at least for a while, the ability of 22
23 labor to resist technological progress. The factory, however, did not solve the problem 23
24 of resistance altogether; unions eventually tried to undermine the ability of the capital- 24
25 ist to exploit the most advanced techniques. Collective action by workers imposed an 25
26 effective limit on the “authority” exercised by capitalists. Workers’ associations tried to 26
27 ban some new techniques altogether or tried to appropriate the entire productivity gains 27
28

29 areas magistrates were persuaded by fear or propaganda that the machine breakers were in the right. The 29
30 tradition of violence in the West of England, writes Randall, deterred all but the most determined innovators. 30
31 Worker resistance was responsible for the slow growth and depression of the industry rather than the reverse 31
32 [Randall (1989)]. The West of England, as a result, lost its supremacy in the wool industry to Yorkshire. 32

33 ⁹² The resistance against sawmills is a good example of attempts to use both legal and illegal means. It 33
34 was widely believed in the eighteenth century that sawmills, like gigmills, were illegal although there is no 34
35 evidence to demonstrate this. When a wind-powered sawmill was constructed at Limehouse (on the Thames, 35
36 near London) in 1768, it was damaged by a mob of sawyers “on the pretence that it deprived many workmen 36
37 of employment” [Cooney (1991)]. 37

38 ⁹³ Jenner’s famous discovery of the smallpox vaccine ran into the opposition of the inoculators concerned 38
39 about losing their lucrative trade [Hopkins (1983, p. 83)]. The source of the vaccine, infected animals, was 39
40 a novelty and led to resistance in and of itself: Clergy objected to the technique because of the “iniquity 39
41 of transferring disease from the beasts of the field to Man” [Cartwright (1977, p. 86)]. Cartoonists depicted 40
41 people acquiring bovine traits, and one woman complained that after he daughter was vaccinated she coughed 41
42 like a cow and grew hairy [Hopkins (1983, p. 84)]. Despite all this, of course, the smallpox vaccine was one 42
43 of the most successful macroinventions of the period of the Industrial Revolution and its inventor became an 43
international celebrity.

1 in terms of higher piece wages, thus weakening the incentive to innovate. On the other 1
2 hand, laborers' industrial actions often led to technological advances aimed specifically 2
3 at crippling s strikes [Bruland (1982) and Rosenberg (1976, pp. 118–119)].⁹⁴ 3
4 4
5 5

6 **9. Conclusions: Technology, growth, and the rise of the occident** 6 7 7

8 In economic history, more so perhaps than in other disciplines, everything is a matter 8
9 of degree, and there are no absolutes. The arguments made in this survey represent an 9
10 interpretation that is by no means generally accepted. Many scholars have argued elo- 10
11 quently and persuasively for continuity rather than radical and abrupt change in western 11
12 society between 1760 and 1830. Almost every element we associate with the Industrial 12
13 Revolution can be seen to have precedent and precursor. Some of these are quite valid 13
14 (episodes of growth and “modernity” can be found in earlier periods; the use of coal 14
15 and non-animate energy was expanding already in the centuries before the Industrial 15
16 Revolution; agricultural productivity may have been as high in 1290 as it was in 1700; 16
17 factory-like settings can be found in earlier periods). Others are based on misapprehen- 17
18 sions (the aeolipiles built by Hero of Alexandria were *not* atmospheric steam engines). 18
19 In the end, the debate on continuity can only be settled if we accept a criterion by which 19
20 to judge the degree of continuity. If the criterion is economic growth, the continuity 20
21 faction in the end will have to concede defeat, even if the victory is one in overtime. 21
22 The Industrial Revolution *itself* was not a period of rapid economic growth, but it is 22
23 clear beyond question that it set into motion an economic process that by the middle 23
24 of the nineteenth century created a material world that followed a dynamic not hitherto 24
25 experienced. 25

26 Not only that growth was faster and more geographically dispersed (covering by 1914 26
27 most of Europe, North America, other European offshoots, and Japan) than had been 27
28 experienced by any economy before, it was sustainable. Unlike previous episodes, it 28
29 kept rolling through the twentieth century. A moment of reflection will underline the 29
30 enormity of this achievement. The twentieth century was in many ways a very bad 30
31 century for the Western world: two horrid World Wars, a hugely costly depression, 31
32 the collapse of international trade after 1914, the disastrous collectivist experiment in 32
33 Russia extended to all of Eastern Europe in 1945, and the loss of its Colonial Empire 33
34 – all of these should have pointed to catastrophe, misery, and a return to economic 34
35 barbarism for the *Abendland*. Something similar may have happened in the fourteenth 35
36 century, the disasters of which in some views set Europe's economy back for a century 36
37 or more. Yet by the early years of the twenty first century, the gap between rich and 37
38 poor nations is bigger than ever and Danny Quah's “twin peaks” are getting further 38
39 and further apart. Despite the huge setbacks, the engine that drove the Occident express 39
40 40
41 41

42 ⁹⁴ The most famous example of an invention triggered by a strike was that of the self-acting mule, invented in 42
43 1825 by Richard Roberts at the prompting of Manchester manufacturers plagued by a strike of mule operators. 43

1 had become so immensely powerful that it easily overwhelmed the twentieth century 1
2 roadblocks that bad luck and human stupidity placed on its tracks. The Great Divergence 2
3 train stormed on, undaunted. 3

4 Social scientists and historians discussing this issue are often accused of “triumphal- 4
5 ism” and “teleologies”, which are paired with “Eurocentricity” or “Western-centricity”. 5
6 Whether the scholars who make such accusations actually mean to argue that the gap 6
7 in income and living standards is imaginary (or ephemeral), or whether they just feel 7
8 that it is unjust and unfair, is sometimes hard to tell.⁹⁵ Yet it seems otiose to gainsay the 8
9 importance of the topic. If the rest of the world is to eventually enjoy the material com- 9
10 forts available to most people in the West or not, we should not give up on our attempt 10
11 to understand “how the West did it”. 11

12 If we want to understand *why* the West did what it did we should ask questions about 12
13 the *when*. The consensus is that by 1750, the gap between the twin peaks was much 13
14 smaller than it was today. If Europe was richer than the rest of the world, it was so 14
15 by a margin that looks thin compared to what it is today. The so-called “California 15
16 School” has been arguing indeed that living standards and measurable indicators of 16
17 economic performance between China and Europe were not all that different by 1750.⁹⁶ 17
18 If this is accepted, and if we are willing to take the Yang-Zhi delta as indicative of 18
19 economic conditions of the non-European world, the current gap between rich and poor 19
20 is largely the result of the Industrial Revolution and the events that followed it. Be 20
21 that as it may, underneath its surface the European soil in 1500 already contained the 21
22 seeds of the future divergence in 1750. There was, however, nothing inexorable about 22
23 what happened after: the seeds need not have sprouted, they could have been washed 23
24 away by the flood of wars, or the young sprouts of future growth might have been 24
25 pulled out by rapacious tax collectors or burned by intolerant religious authorities. There 25
26 could have been a Great *Convergence* after 1800 instead of what actually took place, in 26
27 which Europe would have reverted back to the kind of economic performance prevalent 27
28 in 1500. In the end, the economic history of technology – like all evolutionary sequences 28
29 – contains a deep and irreducible element of contingency. Not all that was had to be. 29

30 The question of “when” is important because it makes geographical explanations that 30
31 explain Europe’s success by its milder climate or conveniently located coal reserves 31
32 less powerful, because these differences are time-invariant. Something had changed in 32
33 Europe before the Industrial Revolution that destabilized the economic dynamic in the 33
34 West, but not elsewhere. The question of “where” is also important. Britain was not 34
35 “Europe”, and even today there are some European regions that clearly are not part of 35
36 the Western economic development pattern or very recent arrivals. On the other hand, 36
37 a number of non-European nations have been able to join the “convergence club”. 37

38 There are two alternative scenarios of the emergence of the gap. One is that, regard- 38
39 less of living standards and income in 1750, Europe was already deeply different from 39
40

42 ⁹⁵ Such confusions mark especially the literature associated with [Gunder Frank \(1998\)](#) and [Blaut \(1993\)](#).

43 ⁹⁶ See especially [Wong \(1997\)](#), [Pomeranz \(2000\)](#) and [Goldstone \(2002\)](#).

1 the rest of the world in 1750 in many respects. In their different ways, David Landes 1
2 (1998), Eric Jones (1981, 1988), Avner Greif (2003) and Angus Maddison (1998) sub- 2
3 scribe to this view. By 1750 Europe had already had Calvin and Newton, Spinoza 3
4 and Galileo, Bacon and Descartes. It had a commercial capitalism thriving especially 4
5 in Atlantic Ports, an institutional structure that supported long-distance trade, a well- 5
6 functioning monetary system, and the ability of rulers to tax their subjects and suppress 6
7 nonconformists and heretics had been constrained in complex but comparatively effec- 7
8 tive ways. It had universities, representative parliamentary bodies, embryonic financial 8
9 institutions, powerful navies and armies, microscopes and printing presses. Its agri- 9
10 culture was gradually switching to more productive rotations, adopting new crops, and 10
11 experimenting with animal breeding. Its manufacturing system was market-oriented and 11
12 competitive. It had established the beginning of a public health system that had con- 12
13 quered the plague (still rampant elsewhere) and was making inroads against smallpox. 13
14 Its ships, aided by sophisticated navigational instruments and maps, had subjugated and 14
15 colonized already some parts of the non-European world and neither the Mongols nor 15
16 the Ottoman Turks were a threat anymore. It drank tea, ate sugar, smoked tobacco, wore 16
17 silk and cotton, and ate from better plates in coal- or peat-heated homes. Its income per 17
18 capita, as well as we can measure it, may have been little different from what it had 18
19 been in the late Middle Ages (though Adam Smith disagreed), yet it was already ahead. 19

20 The alternative school emphasizes that many of these European features could be 20
21 found in other societies, especially in China and Japan, and that when Europe and 21
22 the Orient differed, the difference was not always necessarily conducive to economic 22
23 growth. Ch'ing China may not have been an open economy, but it had law and order, 23
24 a meritocratic bureaucracy, peace, effective property rights, and a great deal of medium- 24
25 and long-distance trade within its borders. We need to be wary from the logical fallacy 25
26 that all initial differences between Europe and China contributed to the outcome. Some 26
27 of the initial difference may have actually worked the other way, so that the Great Di- 27
28 vergence took place despite them. Others were ambiguous in their effect.⁹⁷ In order to 28
29 understand what triggered Europe's economic miracle, we need to identify an event that 29
30 happened before the Industrial Revolution, happened in the right areas, and which can 30
31 be connected logically to subsequent growth. 31

32 I have identified this event as "the Industrial Enlightenment" and have attempted to 32
33 show how it affected the two central elements of the Industrial Revolution, technology 33
34 and institutions, and how these two elements then affected one another. Not everything 34
35 that is normally included in the historians' idea of the Enlightenment mattered, and not 35
36 everything that mattered could be attributed to the Industrial Enlightenment. John Stuart 36
37 Mill's reflection that "the great danger in the study of history is not so much mistaking 37
38 falsehood for truth, as to mistake a part for the whole" should be pertinent here. 38

39
40
41 ⁹⁷ An example is the European States System, often hailed as the element of competition which constrained 41
42 and disciplined European governments into a more rational behavior, lest they weaken their military power. 42
43 Yet the costs of wars may well have exceeded the gains, and the mercantilist policies that the States System 43
44 triggered in the seventeenth century had doubtful effects on economic performance.

1 The emphasis on the Enlightenment illustrates how economists should think about 1
2 culture and cultural beliefs as discussed in great length by Greif (2003). Culture mat- 2
3 tered to economic development – how could it not? But we have to show the exact 3
4 ways in which it mattered and through which channels it operated. I have argued that 4
5 cultural beliefs changed in the eighteenth century, but beyond Greif’s notion of beliefs 5
6 about other people’s behavior, I would include the metaphysical beliefs that people held 6
7 about their environment and the natural world, and their attitudes toward the relationship 7
8 between production and useful knowledge. It should also include their cultural beliefs 8
9 about the possibility and desirability of progress and their notions of economic freedom, 9
10 property, and novelty. 10

11 In that sense, at least, the Enlightenment may have been the missing link that eco- 11
12 nomic historians have hitherto missed. Greif (2003, XIII-17) points out that many of the 12
13 institutional elements of modern Europe were already in place in the late Middle Ages: 13
14 individualism, man-made formal law, corporatism, self governance, and rules that were 14
15 determined through a legislative process in which those who were subject to them could 15
16 be heard and had an input. Yet these elements did not trigger modern growth at that 16
17 time, and it bears reflecting why not. The technological constraints were too confining, 17
18 and the negative feedbacks too strong. 18

19 The story of the growth of the West is the story of the dissolution of these constraints. 19
20 The Baconian belief that the universe is logical and understandable, that the under- 20
21 standing of nature leads to its control, and that control of nature is the surest route to 21
22 increased wealth, was the background of a movement that, although it affected but a 22
23 minute percentage of Europe’s population, played a pivotal role in the emergence of 23
24 modern growth. If culture can be said to matter, it did so because the prevailing ide- 24
25 ology of knowledge among those who mattered started to change in a way it did not 25
26 elsewhere. The eighteenth century Enlightenment, moreover, brought back many of the 26
27 institutional elements of an orderly and civil society, together with the growing real- 27
28 ization, most eloquently expressed by Adam Smith, that economic activity was not a 28
29 zero-sum game and that redistributive institutions and rent-seeking are costly to society. 29
30

31 All the same, ideological changes and cultural developments are not the entire story. 31
32 A desire for improvement and even the “right” kind of institutions by themselves do not 32
33 produce *sustained* growth unless society produces new useful knowledge and unless 33
34 the growth of knowledge can be sustained over time. Useful knowledge grows because 34
35 in each society there are people who are creative and original, and motivated by some 35
36 combination of greed, ambition, curiosity, and altruism. All four of those motives can 36
37 be seen to be operating among the people who helped make the Industrial Revolution, 37
38 often in the same people. Given that the generation of innovations was not yet dominated 38
39 by large corporations, the relative weight of “greed” may have been smaller than in 39
40 the twentieth-first century, and that of curiosity and altruism correspondingly higher, 40
41 though these motives are hard to gauge. Yet in order to be translated from personal 41
42 predilections to facts on the ground, and from there to economic growth, an environment 42
43 that produced the correct incentives and the proper access to knowledge had to exist. The 43

1 uniqueness of the European Enlightenment was that it created that kind of environment 1
2 in addition to the useful knowledge that revolutionized production. 2

3 The experience of the past two centuries in the western world supports the view that 3
4 useful knowledge and its application to production went through a phase transition in 4
5 which it entered a critical region in which equilibrium concepts may no longer apply. 5
6 This means that as far as future technological progress and economic growth are concerned, 6
7 not even the sky is the limit. Science Fiction writers have known this all along. 7
