

# Simple New Keynesian Model without Capital: Implications of Networks

Lawrence J. Christiano

Gerzensee, August 2016

# Objectives

- Provide a rigorous development of the basic New Keynesian model without capital.
  - Previous exposure to the model is helpful, but not absolutely necessary.
- Present a version of the model that incorporates a simple formulation of the ‘network’ nature of production.
  - In standard model, all production is sold directly to final purchasers.
  - In fact (see, e.g., Basu AER1996) about 1/2 of gross production by firms is sold to other firms.
    - See Christiano, Trabandt and Walentin (Handbook of Monetary Economics, 2011) for an extended discussion of the approach to networks developed here.

# Implications of thinking about networks

- Obtain a quantitatively important theory of the cost of inflation.
- Raise questions about the effectiveness of inflation targeting as a device for stabilizing inflation and the macroeconomy.
- Flatten the slope of the Phillips curve because of strategic complementarities in price setting.

## Background Readings on Networks

- Basu, Susanto, 1995, 'Intermediate goods and business cycles: Implications for productivity and welfare,' *American Economic Review*, 85 (3), 512–531.
- Rotemberg, J., and M. Woodford, 1995, 'Dynamic General Equilibrium Models with Imperfectly Competitive Product Markets,' in, T. Cooley, ed., *Frontiers of Business Cycle Research*, Princeton University Press (also, NBER wp 4502).
- Nakamura, Emi and Jon Steinsson, 2010, 'Monetary Non-Neutrality in a Multisector Menu Cost Model,' *The Quarterly Journal of Economics*, August.

# Households

- Problem:

$$\max E_0 \sum_{t=0}^{\infty} \beta^t \left( \log C_t - \exp(\tau_t) \frac{N_t^{1+\varphi}}{1+\varphi} \right), \quad \tau_t = \lambda \tau_{t-1} + \varepsilon_t^\tau$$

s.t.  $P_t C_t + B_{t+1} \leq W_t N_t + R_{t-1} B_t + \text{Profits net of taxes}_t$

- First order conditions:

$$\frac{1}{C_t} = \beta E_t \frac{1}{C_{t+1}} \frac{R_t}{\bar{\pi}_{t+1}} \quad (5)$$
$$\exp(\tau_t) C_t N_t^\varphi = \frac{W_t}{P_t}.$$

# Goods Production

- A homogeneous final good is produced using the following (Dixit-Stiglitz) production function:

$$Y_t = \left[ \int_0^1 Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di \right]^{\frac{\varepsilon}{\varepsilon-1}}.$$

- Each intermediate good,  $Y_{i,t}$ , is produced as follows:

$$Y_{i,t} = \exp(a_t) N_{i,t}^\gamma I_{i,t}^{1-\gamma}, \quad a_t \sim \text{exogenous shock to technology}, \\ 0 < \gamma \leq 1.$$

- $I_{i,t}$   $\sim$  'materials' these are purchases of the homogeneous output good (Basu's simplified way of capturing that firms buy goods from other firms).
- Before discussing the firms that operate these production functions, we briefly investigate the socially efficient ('First Best') allocation of resources across  $i$ .
  - simplify the discussion with  $\gamma = 1$  (no materials).

# Efficient Sectoral Allocation of Resources Across Sectors

- With Dixit-Stiglitz final good production function, there is a socially optimal allocation of resources to all the intermediate activities,  $Y_{i,t}$ 
  - It is optimal to run them all at the same rate, *i.e.*,  $Y_{i,t} = Y_{j,t}$  for all  $i, j \in [0, 1]$ .
- For given  $N_t$ , it is optimal to set  $N_{i,t} = N_{j,t}$ , for all  $i, j \in [0, 1]$
- In this case, final output is given by

$$Y_t = e^{at} N_t.$$

- Best way to see this is to suppose that labor is *not* allocated equally to all activities.
  - Explore one simple deviation from  $N_{i,t} = N_{j,t}$  for all  $i, j \in [0, 1]$ .

## Suppose Labor *Not* Allocated Equally

- Example:

$$N_{it} = \begin{cases} 2\alpha N_t & i \in [0, \frac{1}{2}] \\ 2(1 - \alpha)N_t & i \in [\frac{1}{2}, 1] \end{cases}, \quad 0 \leq \alpha \leq 1.$$

- Note that this is a particular distribution of labor across activities:

$$\int_0^1 N_{it} di = \frac{1}{2} 2\alpha N_t + \frac{1}{2} 2(1 - \alpha)N_t = N_t$$

# Labor *Not* Allocated Equally, cnt'd

$$\begin{aligned} Y_t &= \left[ \int_0^1 Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di \right]^{\frac{\varepsilon}{\varepsilon-1}} \\ &= \left[ \int_0^{\frac{1}{2}} Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di + \int_{\frac{1}{2}}^1 Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di \right]^{\frac{\varepsilon}{\varepsilon-1}} \\ &= e^{a_t} \left[ \int_0^{\frac{1}{2}} N_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di + \int_{\frac{1}{2}}^1 N_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di \right]^{\frac{\varepsilon}{\varepsilon-1}} \\ &= e^{a_t} \left[ \int_0^{\frac{1}{2}} (2\alpha N_t)^{\frac{\varepsilon-1}{\varepsilon}} di + \int_{\frac{1}{2}}^1 (2(1-\alpha)N_t)^{\frac{\varepsilon-1}{\varepsilon}} di \right]^{\frac{\varepsilon}{\varepsilon-1}} \\ &= e^{a_t} N_t \left[ \int_0^{\frac{1}{2}} (2\alpha)^{\frac{\varepsilon-1}{\varepsilon}} di + \int_{\frac{1}{2}}^1 (2(1-\alpha))^{\frac{\varepsilon-1}{\varepsilon}} di \right]^{\frac{\varepsilon}{\varepsilon-1}} \\ &= e^{a_t} N_t \left[ \frac{1}{2} (2\alpha)^{\frac{\varepsilon-1}{\varepsilon}} + \frac{1}{2} (2(1-\alpha))^{\frac{\varepsilon-1}{\varepsilon}} \right]^{\frac{\varepsilon}{\varepsilon-1}} \\ &= e^{a_t} N_t f(\alpha) \end{aligned}$$

$$f(\alpha) = \left[ \frac{1}{2} (2\alpha)^{\frac{\varepsilon-1}{\varepsilon}} + \frac{1}{2} (2(1-\alpha))^{\frac{\varepsilon-1}{\varepsilon}} \right]^{\frac{\varepsilon}{\varepsilon-1}}$$

Efficient Resource Allocation Means Equal Labor Across All Sectors

# Homogeneous Goods Production

- Competitive firms:
  - maximize profits:

$$P_t Y_t - \int_0^1 P_{i,t} Y_{i,t} dj,$$

subject to:

$$Y_t = \left[ \int_0^1 Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} dj \right]^{\frac{\varepsilon}{\varepsilon-1}}.$$

- Foncs:

$$Y_{i,t} = Y_t \left( \frac{P_t}{P_{i,t}} \right)^\varepsilon \rightarrow P_t = \overbrace{\left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{1}{1-\varepsilon}}}^{\text{"cross price restrictions"}}$$

# Intermediate Goods Production

- Demand curve for  $i^{th}$  monopolist:

$$Y_{i,t} = Y_t \left( \frac{P_t}{P_{i,t}} \right)^\varepsilon .$$

- Production function:

$$Y_{i,t} = \exp(a_t) N_{i,t}^\gamma I_{i,t}^{1-\gamma}, \quad a_t \sim \text{exogenous shock to technology,} \\ 0 < \gamma \leq 1.$$

- $I_{i,t}$  ~ 'materials' these are purchases of the homogeneous output good (Basu's simplified way of capturing that firms buy goods from other firms).
- Calvo Price-Setting Friction:

$$P_{i,t} = \begin{cases} \tilde{P}_t & \text{with probability } 1 - \theta \\ P_{i,t-1} & \text{with probability } \theta \end{cases} .$$

# Cost Minimization Problem

- Price setting by intermediate good firms is discussed later.
  - The intermediate good firm must produce the quantity demanded,  $Y_{i,t}$ , at the price that it sets.
  - Right now we take  $Y_{i,t}$  as given and we investigate the cost minimization problem that determines the firm's choice of inputs.

Cost minimization problem:

$$\min_{N_{i,t}, I_{i,t}} \bar{W}_t N_{i,t} + \bar{P}_t I_{i,t} + \underbrace{\lambda_{i,t}}_{\text{marginal cost (money terms)}} \left[ Y_{i,t} - A_t N_{i,t}^\gamma I_{i,t}^{1-\gamma} \right]$$

with resource costs:

$$\bar{W}_t = \underbrace{(1 - \nu)}_{\text{subsidy, if } \nu > 0} \times \underbrace{(1 - \psi + \psi R_t) W_t}_{\text{cost, including finance, of a unit of labor}}$$

$$\bar{P}_t = (1 - \nu) \times \underbrace{(1 - \psi + \psi R_t) P_t}_{\text{cost, including finance, of a unit of materials}} .$$

# Cost Minimization Problem

- Problem:

$$\min_{N_{i,t}, I_{i,t}} \bar{W}_t N_{i,t} + \bar{P}_t I_{i,t} + \lambda_{i,t} \left[ Y_{i,t} - A_t N_{i,t}^\gamma I_{i,t}^{1-\gamma} \right]$$

- First order conditions:

$$\bar{P}_t I_{i,t} = (1 - \gamma) \lambda_{i,t} Y_{i,t}, \quad \bar{W}_t N_{i,t} = \gamma \lambda_{i,t} Y_{i,t},$$

so that,

$$\begin{aligned} \frac{I_{it}}{N_{it}} &= \frac{1 - \gamma}{\gamma} \frac{\bar{W}_t}{\bar{P}_t} = \frac{1 - \gamma}{\gamma} \exp(\tau_t) C_t N_t^\varphi \\ &\rightarrow \frac{I_{it}}{N_{it}} = \frac{I_t}{N_t}, \text{ for all } i. \end{aligned}$$

# Cost Minimization Problem

- Firm first order conditions imply

$$\lambda_{i,t} = \left( \frac{\bar{P}_t}{1 - \gamma} \right)^{1-\gamma} \left( \frac{\bar{W}_t}{\gamma} \right)^\gamma \frac{1}{A_t}.$$

- Divide marginal cost by  $P_t$  :

$$s_t \equiv \frac{\lambda_{i,t}}{P_t} = (1 - \nu) (1 - \psi + \psi R_t) \left( \frac{1}{1 - \gamma} \right)^{1-\gamma} \\ \times \left( \frac{1}{\gamma} \exp(\tau_t) C_t N_t^\varphi \right)^\gamma \frac{1}{A_t} \quad (9),$$

after substituting out for  $\bar{P}_t$  and  $\bar{W}_t$  and using the household's labor first order condition.

- Note from (9) that  $i^{th}$  firm's marginal cost,  $s_t$ , is independent of  $i$  and  $Y_{it}$ .

# Share of Materials in Intermediate Good Output

- Firm  $i$  materials proportional to  $Y_{i,t}$  :

$$I_{i,t} = \frac{(1 - \gamma) \lambda_{i,t} Y_{i,t}}{\bar{P}_t} = \mu_t Y_{i,t},$$

where

$$\mu_t = \frac{(1 - \gamma) s_t}{(1 - \nu) (1 - \psi + \psi R_t)} \quad (10).$$

- "Share of materials in firm-level gross output",  $\mu_t$ .

# Decision By Firm that Can Change Its Price

- $i^{th}$  intermediate good firm's objective:

$$E_t^i \sum_{j=0}^{\infty} \beta^j v_{t+j} \overbrace{\left[ \overbrace{P_{i,t+j} Y_{i,t+j}}^{\text{revenues}} - \overbrace{P_{t+j} s_{t+j} Y_{i,t+j}}^{\text{total cost}} \right]}^{\text{period } t+j \text{ profits sent to household}}$$

$v_{t+j}$  - Lagrange multiplier on household budget constraint

- Firm that gets to reoptimize its price is concerned only with future states in which it does not change its price:

$$\begin{aligned} & E_t^i \sum_{j=0}^{\infty} \beta^j v_{t+j} [P_{i,t+j} Y_{i,t+j} - P_{t+j} s_{t+j} Y_{i,t+j}] \\ &= E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} [\tilde{P}_t Y_{i,t+j} - P_{t+j} s_{t+j} Y_{i,t+j}] + X_t, \end{aligned}$$

where  $\tilde{P}_t$  denotes a firm's price-setting choice at time  $t$  and  $X_t$  not a function of  $\tilde{P}_t$ .

# Decision By Firm that Can Change Its Price

- Substitute out demand curve:

$$\begin{aligned} & E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} [\tilde{P}_t Y_{i,t+j} - P_{t+j} s_{t+j} Y_{i,t+j}] \\ &= E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} Y_{t+j} P_{t+j}^{\epsilon} \left[ \tilde{P}_t^{1-\epsilon} - P_{t+j} s_{t+j} \tilde{P}_t^{-\epsilon} \right]. \end{aligned}$$

- Differentiate with respect to  $\tilde{P}_t$  :

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} Y_{t+j} P_{t+j}^{\epsilon} \left[ (1 - \epsilon) (\tilde{P}_t)^{-\epsilon} + \epsilon P_{t+j} s_{t+j} \tilde{P}_t^{-\epsilon-1} \right] = 0,$$

or,

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} Y_{t+j} P_{t+j}^{\epsilon+1} \left[ \frac{\tilde{P}_t}{P_{t+j}} - \frac{\epsilon}{\epsilon - 1} s_{t+j} \right] = 0.$$

- When  $\theta = 0$ , get standard result - price is fixed markup over marginal cost.

# Decision By Firm that Can Change Its Price

- Substitute out the multiplier:

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j \overbrace{u'(C_{t+j})}^{= v_{t+j}} \frac{Y_{t+j} P_{t+j}^{\varepsilon+1}}{P_{t+j}} \left[ \frac{\tilde{P}_t}{P_{t+j}} - \frac{\varepsilon}{\varepsilon-1} s_{t+j} \right] = 0.$$

- Using assumed log-form of utility,

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{-\varepsilon} \left[ \tilde{p}_t X_{t,j} - \frac{\varepsilon}{\varepsilon-1} s_{t+j} \right] = 0,$$

$$\tilde{p}_t \equiv \frac{\tilde{P}_t}{P_t}, \quad \bar{\pi}_t \equiv \frac{P_t}{P_{t-1}}, \quad X_{t,j} = \begin{cases} \frac{1}{\bar{\pi}_{t+j}\bar{\pi}_{t+j-1}\dots\bar{\pi}_{t+1}}, & j \geq 1 \\ 1, & j = 0. \end{cases},$$

'recursive property':  $X_{t,j} = X_{t+1,j-1} \frac{1}{\bar{\pi}_{t+1}}, j > 0$

# Decision By Firm that Can Change Its Price

- Want  $\tilde{p}_t$  in:

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{-\varepsilon} \left[ \tilde{p}_t X_{t,j} - \frac{\varepsilon}{\varepsilon-1} s_{t+j} \right] = 0$$

- Solving for  $\tilde{p}_t$ , we conclude that prices are set as follows:

$$\tilde{p}_t = \frac{E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+1}} (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j}}{E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{1-\varepsilon}} = \frac{K_t}{F_t}.$$

- Need convenient expressions for  $K_t$ ,  $F_t$ .

## Simplifying Numerator

$$\begin{aligned}K_t &= E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} S_{t+j} \\&= \frac{\varepsilon}{\varepsilon - 1} \frac{Y_t}{C_t} S_t \\&\quad + \beta\theta E_t \sum_{j=1}^{\infty} (\beta\theta)^{j-1} \frac{Y_{t+j}}{C_{t+j}} \left( \overbrace{\frac{1}{\bar{\pi}_{t+1}} X_{t+1,j-1}}^{=X_{t,j}, \text{ recursive property}} \right)^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} S_{t+j} \\&= \frac{\varepsilon}{\varepsilon - 1} \frac{Y_t}{C_t} S_t + \mathcal{Z}_t,\end{aligned}$$

where

$$\mathcal{Z}_t = \beta\theta E_t \sum_{j=1}^{\infty} (\beta\theta)^{j-1} \frac{Y_{t+j}}{C_{t+j}} \left( \frac{1}{\bar{\pi}_{t+1}} X_{t+1,j-1} \right)^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} S_{t+j}$$

## Simplifying Numerator, cnt'd

$$K_t = E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j} = \frac{\varepsilon}{\varepsilon-1} \frac{Y_t}{C_t} s_t + Z_t$$

$$\begin{aligned} Z_t &= \beta\theta E_t \sum_{j=1}^{\infty} (\beta\theta)^{j-1} \frac{Y_{t+j}}{C_{t+j}} \left( \frac{1}{\bar{\pi}_{t+1}} X_{t+1,j-1} \right)^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j} \\ &= \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j+1}}{C_{t+j+1}} X_{t+1,j}^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+1+j} \\ &= \beta\theta \overbrace{E_t E_{t+1}}^{=E_t \text{ by LIME}} \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j+1}}{C_{t+j+1}} X_{t+1,j}^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+1+j} \\ &= \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} \underbrace{E_{t+1} \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j+1}}{C_{t+j+1}} X_{t+1,j}^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+1+j}}_{\text{exactly } K_{t+1}!} \end{aligned}$$

# Decision By Firm that Can Change Its Price

- Recall,

$$\tilde{p}_t = \frac{E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j}}{E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{1-\varepsilon}} = \frac{K_t}{F_t}$$

- We have shown that the numerator has the following simple representation:

$$\begin{aligned} K_t &= E_t \sum_{j=0}^{\infty} (\beta\theta)^j \frac{Y_{t+j}}{C_{t+j}} (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j} \\ &= \frac{\varepsilon}{\varepsilon-1} \frac{Y_t}{C_t} s_t + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} K_{t+1} \quad (1) \end{aligned}$$

- Similarly,

$$F_t = \frac{Y_t}{C_t} + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{1-\varepsilon} F_{t+1} \quad (2)$$

# Interpretation of Price Formula

- Note,

$$\frac{1}{P_{t+j}} = \frac{1}{P_t} X_{t,j}, \quad s_{t+j} = \frac{\lambda_{t+j}}{P_{t+j}} = \frac{\lambda_{t+j}}{P_t} X_{t,j}, \quad \tilde{p}_t = \frac{\tilde{P}_t}{P_t}.$$

Multiply both sides of the expression for  $\tilde{p}_t$  by  $P_t$  :

$$\tilde{P}_t = \frac{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{1-\varepsilon} \frac{Y_{t+j}}{C_{t+j}} \frac{\varepsilon}{\varepsilon-1} \lambda_{t+j}}{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{1-\varepsilon} \frac{Y_{t+j}}{C_{t+j}}} = \frac{\varepsilon}{\varepsilon-1} \sum_{j=0}^{\infty} E_t \omega_{t+j} \lambda_{t+j}$$

where

$$\omega_{t+j} = \frac{(\beta\theta)^j (X_{t,j})^{1-\varepsilon} \frac{Y_{t+j}}{C_{t+j}}}{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{1-\varepsilon} \frac{Y_{t+j}}{C_{t+j}}}, \quad \sum_{j=0}^{\infty} E_t \omega_{t+j} = 1.$$

Evidently, price is set as a markup over a weighted average of future marginal cost, where the weights are shifted into the future depending on how big  $\theta$  is.

# Moving On to Aggregates

- Aggregate price level.
- Aggregate measures of production.
  - Value added.
  - Gross output.

# Aggregate Price Index

- Rewrite the aggregate price index.
  - let  $p \in (0, \infty)$  the set of logically possible prices for intermediate good producers.
  - let  $g_t(p) \geq 0$  denote the measure (e.g., 'number') of producers that have price,  $p$ , in  $t$
  - let  $g_{t-1,t}(p) \geq 0$ , denote the measure of producers that had price,  $p$ , in  $t - 1$  and could not reoptimize in  $t$
- Then,

$$P_t = \left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{1}{1-\varepsilon}} = \left( \int_0^\infty g_t(p) p^{(1-\varepsilon)} dp \right)^{\frac{1}{1-\varepsilon}} .$$

- Note:

$$P_t = \left( (1 - \theta) \tilde{P}_t^{1-\varepsilon} + \int_0^\infty g_{t-1,t}(p) p^{(1-\varepsilon)} dp \right)^{\frac{1}{1-\varepsilon}} .$$

# Aggregate Price Index

- Calvo randomization assumption:

measure of firms that had price,  $p$ , in  $t-1$  and could not change

$$\overbrace{g_{t-1,t}(p)}$$

measure of firms that had price  $p$  in  $t-1$

$$= \theta \times \overbrace{g_{t-1}(p)}$$

- Then,

$$P_t = \left( (1 - \theta) \tilde{P}_t^{1-\varepsilon} + \int_0^\infty g_{t-1,t}(p) p^{(1-\varepsilon)} dp \right)^{\frac{1}{1-\varepsilon}}$$
$$= \left( (1 - \theta) \tilde{P}_t^{1-\varepsilon} + \theta \overbrace{\int_0^\infty g_{t-1}(p) p^{(1-\varepsilon)} dp}^{=P_{t-1}^{1-\varepsilon}} \right)^{\frac{1}{1-\varepsilon}}$$

# Restriction Between Aggregate and Intermediate Good Prices

- 'Calvo result':

$$P_t = \left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{1}{1-\varepsilon}} = \left[ (1-\theta) \tilde{P}_t^{(1-\varepsilon)} + \theta P_{t-1}^{(1-\varepsilon)} \right]^{\frac{1}{1-\varepsilon}} .$$

- Divide by  $P_t$  :

$$1 = \left[ (1-\theta) \tilde{p}_t^{(1-\varepsilon)} + \theta \left( \frac{1}{\bar{\pi}_t} \right)^{(1-\varepsilon)} \right]^{\frac{1}{1-\varepsilon}} .$$

- Rearrange:

$$\tilde{p}_t = \left[ \frac{1-\theta}{1-\theta \bar{\pi}_t^{(\varepsilon-1)}} \right]^{\frac{1}{\varepsilon-1}}$$

# Aggregate inputs and outputs

- *Gross output* of firm  $i$  :

$$Y_{i,t} = \exp(a_t) N_{i,t}^\gamma I_{i,t}^{1-\gamma}.$$

- Net output or *value-added* would subtract out the materials that were bought from other firms.

- Economy-wide *gross output*: sum of value of  $Y_{i,t}$  across all firms:

$$\begin{aligned} \int_0^1 P_{i,t} Y_{i,t} di &= \int_0^1 P_t \left( \frac{Y_t}{Y_{i,t}} \right)^{\frac{1}{\varepsilon}} Y_{i,t} di \\ &= P_t Y_t^{\frac{\varepsilon-1}{\varepsilon}} \int_0^1 Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di = P_t Y_t. \end{aligned}$$

- *Gross output production function*: relation between  $Y_t$  and non-produced inputs,  $N_t$ .

# Aggregate inputs and outputs, cnt'd

- Gross output,  $Y_t$ , is not a good measure of economic output, because it double counts.
  - Some of the output that firm  $i$  'produced' is materials produced by another firm, which is counted in that firm's output.
  - If wheat is used to make bread, wrong to measure production by adding all wheat and all bread. That double counts the wheat.
- Want aggregate *value-added*: sum of firm-level gross output, minus purchases of materials from other firms.
- *Value-added production function*: expression relating aggregate value-added in period  $t$  to inputs not produced in period  $t$ .
  - capital and labor.

# Gross Output vs Agg Materials and Labor

- Approach developed by Tack Yun (JME, 1996).
- Define  $Y_t^*$ :

$$\begin{aligned} Y_t^* &\equiv \int_0^1 Y_{i,t} di \\ &\quad \underbrace{\hspace{1.5cm}}_{\text{demand curve}} Y_t \int_0^1 \left( \frac{P_{i,t}}{P_t} \right)^{-\varepsilon} di = Y_t P_t^\varepsilon \int_0^1 (P_{i,t})^{-\varepsilon} di \\ &= Y_t P_t^\varepsilon (P_t^*)^{-\varepsilon} \end{aligned}$$

where, using 'Calvo result':

$$P_t^* \equiv \left[ \int_0^1 P_{i,t}^{-\varepsilon} di \right]^{\frac{-1}{\varepsilon}} = \left[ (1 - \theta) \tilde{P}_t^{-\varepsilon} + \theta (P_{t-1}^*)^{-\varepsilon} \right]^{\frac{-1}{\varepsilon}}$$

- Then

$$Y_t = p_t^* Y_t^*, \quad p_t^* = \left( \frac{P_t^*}{P_t} \right)^\varepsilon.$$

# Gross Output vs Agg Materials and Labor

- Relationship between aggregate inputs and outputs:

$$\begin{aligned} Y_t &= p_t^* Y_t^* = p_t^* \int_0^1 Y_{i,t} di \\ &= p_t^* A_t \int_0^1 N_{i,t}^\gamma I_{i,t}^{1-\gamma} di = p_t^* A_t \int_0^1 \left( \frac{N_{i,t}}{I_{i,t}} \right)^\gamma I_{i,t} di, \\ &= p_t^* A_t \left( \frac{N_t}{I_t} \right)^\gamma I_t, \end{aligned}$$

or,

$$Y_t = p_t^* A_t N_t^\gamma I_t^{1-\gamma} \quad (6).$$

- Note that  $p_t^*$  is a function of the ratio of two averages (with different weights) of  $P_{i,t}$ ,  $i \in (0, 1)$ 
  - So, when  $P_{i,t} = P_{j,t}$  for all  $i, j \in (0, 1)$ , then  $p_t^* = 1$ .
  - But, what is  $p_t^*$  when  $P_{i,t} \neq P_{j,t}$  for some  $i, j \in (0, 1)$ ?

# Tack Yun Distortion

- Consider the object,

$$p_t^* = \left( \frac{P_t^*}{P_t} \right)^\varepsilon,$$

where

$$P_t^* = \left( \int_0^1 P_{i,t}^{-\varepsilon} di \right)^{\frac{-1}{\varepsilon}}, \quad P_t = \left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{1}{1-\varepsilon}}$$

- In following slide, use Jensen's inequality to show:

$$p_t^* \leq 1.$$

# Tack Yun Distortion

- Let  $f(x) = x^4$ , a convex function. Then,

$$\text{convexity: } \alpha x_1^4 + (1 - \alpha) x_2^4 > (\alpha x_1 + (1 - \alpha) x_2)^4$$

for  $x_1 \neq x_2$ ,  $0 < \alpha < 1$ .

- Applying this idea to prices:

$$\begin{aligned} \text{convexity: } \int_0^1 \left( P_{i,t}^{(1-\varepsilon)} \right)^{\frac{\varepsilon}{\varepsilon-1}} di &\geq \left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{\varepsilon}{\varepsilon-1}} \\ \iff \left( \int_0^1 P_{i,t}^{-\varepsilon} di \right) &\geq \left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{\varepsilon}{\varepsilon-1}} \\ \iff \underbrace{\left( \int_0^1 P_{i,t}^{-\varepsilon} di \right)^{\frac{-1}{\varepsilon}}}_{P_t^*} &\leq \underbrace{\left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{1}{1-\varepsilon}}}_{P_t} \end{aligned}$$

# Law of Motion of Tack Yun Distortion

- We have

$$P_t^* = \left[ (1 - \theta) \tilde{P}_t^{-\varepsilon} + \theta (P_{t-1}^*)^{-\varepsilon} \right]^{\frac{-1}{\varepsilon}}$$

- Then,

$$\begin{aligned} p_t^* &\equiv \left( \frac{P_t^*}{P_t} \right)^\varepsilon = \left[ (1 - \theta) \tilde{p}_t^{-\varepsilon} + \theta \frac{\bar{\pi}_t^\varepsilon}{p_{t-1}^*} \right]^{-1} \\ &= \left[ (1 - \theta) \left( \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right)^{\frac{\varepsilon}{\varepsilon-1}} + \frac{\theta \bar{\pi}_t^\varepsilon}{p_{t-1}^*} \right]^{-1} \quad (4) \end{aligned}$$

using the restriction between  $\tilde{p}_t$  and aggregate inflation developed earlier.

# Gross Output Production Function

- Recall

$$I_{i,t} = \mu_t Y_{i,t},$$

so,

$$I_t \equiv \int_0^1 I_{i,t} di = \mu_t \int_0^1 Y_{i,t} di = \mu_t Y_t^* = \frac{\mu_t}{p_t^*} Y_t.$$

- Then, the gross output production function is:

$$\begin{aligned} Y_t &= p_t^* A_t N_t^\gamma I_t^{1-\gamma} \\ &= p_t^* A_t N_t^\gamma \left( \frac{\mu_t}{p_t^*} Y_t \right)^{1-\gamma} \\ \longrightarrow Y_t &= \left( p_t^* A_t \left( \frac{\mu_t}{p_t^*} \right)^{1-\gamma} \right)^{\frac{1}{\gamma}} N_t \end{aligned}$$

# Value Added (GDP) Production Function

- We have

$$\begin{aligned}GDP_t &= Y_t - I_t = \left(1 - \frac{\mu_t}{p_t^*}\right) Y_t \\&= \underbrace{\left(1 - \frac{\mu_t}{p_t^*}\right) \left(p_t^* A_t \left(\frac{\mu_t}{p_t^*}\right)^{1-\gamma}\right)}_{\text{=Total Factor Productivity (TFP)}}^{\frac{1}{\gamma}} N_t \\&= \left(p_t^* A_t \left(1 - \frac{\mu_t}{p_t^*}\right)^\gamma \left(\frac{\mu_t}{p_t^*}\right)^{1-\gamma}\right)^{\frac{1}{\gamma}} N_t\end{aligned}$$

- Note how an increase in technology at the firm level, by  $A_t$ , gives rise to a bigger increase in TFP by  $A_t^{1/\gamma}$ .
  - In the literature on networks,  $1/\gamma$  is referred to as a ‘multiplier effect’ (see Jones, 2011).
- The Tack Yun distortion,  $p_t^*$ , is associated with the same multiplier phenomenon.

# Decomposition for TFP

- To maximize  $GDP$  for given aggregate  $N_t$  and  $A_t$  :

$$\max_{0 < p_t^* \leq 1, 0 \leq \lambda_t \leq 1} \left( p_t^* A_t (1 - \lambda_t)^\gamma (\lambda_t)^{1-\gamma} \right)^{\frac{1}{\gamma}}$$
$$\rightarrow \lambda_t = 1 - \gamma, p_t^* = 1.$$

- So,

$$TFP_t = \underbrace{\left( p_t^* \left( \frac{1 - \frac{\mu_t}{p_t^*}}{\gamma} \right)^\gamma \left( \frac{\frac{\mu_t}{p_t^*}}{1 - \gamma} \right)^{1-\gamma} \right)^{\frac{1}{\gamma}}}_{\text{Component due to market distortions} \equiv \chi_t}$$
$$\times \underbrace{\left( A_t (\gamma)^\gamma (1 - \gamma)^{1-\gamma} \right)^{\frac{1}{\gamma}}}_{\text{Exogenous, technology component} \equiv \tilde{A}_t}$$

# Evaluating the Distortions

- The equations characterizing the TFP distortion,  $\chi_t$  :

$$\chi_t = \left( p_t^* \left( \frac{1 - \frac{\mu_t}{p_t^*}}{\gamma} \right)^\gamma \left( \frac{\frac{\mu_t}{p_t^*}}{1 - \gamma} \right)^{1-\gamma} \right)^{\frac{1}{\gamma}}$$
$$p_t^* = \left[ (1 - \theta) \left( \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right)^{\frac{\varepsilon}{\varepsilon-1}} + \frac{\theta \bar{\pi}_t^\varepsilon}{p_{t-1}^*} \right]^{-1}.$$

- Potentially, NK model provides an 'endogenous theory of TFP'.
- Standard practice in NK literature is to set  $\chi_t = 1$  for all  $t$ .
  - Set  $\gamma = 1$  and linearize around  $\bar{\pi}_t = p_t^* = 1$ .
  - With  $\gamma = 1$ ,  $\chi_t = p_t^*$ , and first order expansion of  $p_t^*$  around  $\bar{\pi}_t = p_t^* = 1$  is:

$$p_t^* = p^* + 0 \times \bar{\pi}_t + \theta (p_{t-1}^* - p^*), \text{ with } p^* = 1,$$

so  $p_t^* \rightarrow 1$  and is invariant to shocks.

# Empirical Assessment of the Distortions

- First, do 'back of the envelope' calculations in a steady state when inflation is constant and  $p^*$  is constant.

$$p^* = \left[ (1 - \theta) \left( \frac{1 - \theta \bar{\pi}^{(\varepsilon-1)}}{1 - \theta} \right)^{\frac{\varepsilon}{\varepsilon-1}} + \frac{\theta \bar{\pi}^\varepsilon}{p^*} \right]^{-1}$$
$$\rightarrow p^* = \frac{1 - \theta \bar{\pi}^\varepsilon}{1 - \theta} \left( \frac{1 - \theta}{1 - \theta \bar{\pi}^{(\varepsilon-1)}} \right)^{\frac{\varepsilon}{\varepsilon-1}}$$

- Approximate TFP distortion,  $\chi$  :

$$\chi_t = \left( p_t^* \left( \frac{1 - \frac{\mu_t}{p_t^*}}{\gamma} \right)^\gamma \left( \frac{\frac{\mu_t}{p_t^*}}{1 - \gamma} \right)^{1-\gamma} \right)^{\frac{1}{\gamma}} \underbrace{\text{more on this later}}_{\simeq} (p^*)^{1/\gamma}$$

# Three Inflation Rates:

- Average inflation in the 1970s, 8 percent APR.
- Several people have suggested that the US raise its inflation target to 4 percent to raise the nominal rate of interest and thereby reduce the likelihood of the zero lower bound on the interest rate becoming binding again.
  - <http://www.voxeu.org/article/case-4-inflation>
- Two percent inflation is the average in the recent (pre-2008) low inflation environment.

# Cost of Three Alternative Permanent Levels of Inflation

$$p^* = \frac{1 - \theta \bar{\pi}^\varepsilon}{1 - \theta} \left( \frac{1 - \theta}{1 - \theta \bar{\pi}^{(\varepsilon-1)}} \right)^{\frac{\varepsilon}{\varepsilon-1}}, \quad \chi = (p^*)^{1/\gamma}$$

<b>Table 1: Percent of GDP Lost<sup>1</sup> Due to Inflation, 100(1 - <math>\chi_t</math>)</b>	
Without networks ( $\gamma = 1$ )	With networks ( $\gamma = 1/2$ )
<b>a: Steady state inflation: 8 percent per year</b>	
2.41 <sup>2</sup> (3.92) [10.85]	4.76 (7.68) [20.53]
<b>b: Steady state inflation: 4 percent per year</b>	
0.46 (0.64) [1.13]	0.91 (1.27) [2.25]
<b>c: Steady state inflation: 2 percent per year</b>	
0.10 (0.13) [0.21]	0.20 (0.27) [0.42]
Note: number not in parentheses assumes a markup of 20 percent; number in parentheses: 15 percent; number in square brackets: 10 percent	

# **Next: Assess Costs of Inflation Using Non-Steady State Formulas**

Figure 1a: Percent loss of GDP due to Inflation, assumed markup is 1.2

Figure 1b: Percent loss of GDP due to Inflation, assumed markup is 1.15

# Inflation Distortions Displayed are Big

- With  $\varepsilon = 6$ ,
  - $\text{mean}(\chi_t) = 0.98$ , a 2% loss of GDP.
  - frequency,  $\chi_t < 0.955$ , is 10% (i.e., 10% of the time, the output loss is greater than 4.5 percent).
- With more competition (i.e.,  $\varepsilon$  higher), the losses are greater.
  - with higher elasticity of demand, given movements in inflation imply much greater substitution away from high priced items, thus greater misallocation (caveat: this intuition is incomplete since with greater  $\varepsilon$  the consequences of a given amount of misallocation are smaller).
- Distortions with  $\gamma = 1/2$  are roughly twice the size of distortions in standard case,  $\gamma = 1$ .
  - To see this, note

$$1 - \chi_t \simeq 1 - (p^*)^{\frac{1}{\gamma}} \quad \underbrace{\hspace{1.5cm}}_{\simeq} \quad \overset{\text{Taylor series expansion about } p^*=1}{\frac{1}{\gamma}} (1 - p^*).$$

# Comparison of Steady State and Dynamic Costs of Inflation in 1970s

- Results

	No networks, $\gamma = 1$	Networks, $\gamma = 2$
Steady state lost output	2.41 (3.92)*	4.76 (7.68)
Mean, 1972Q1-1982Q4	3.13 (5.22)	6.26 (10.44)
Note * number not in parentheses - markup of 20 percent (i.e., $\varepsilon = 6$ )		
number in parentheses - markup of 15 percent. (i.e., $\varepsilon = 7.7$ )		

- Evidently, distortions increase rapidly in inflation,

$$E [\textit{distortion} (\textit{inflation})] > \textit{distortion} (E\textit{inflation})$$

# Next

- Collect the equilibrium conditions.
  - For careful comparison of NK model with RBC model, see [http://faculty.wcas.northwestern.edu/~lchrist/course/China\\_Chengdu\\_2016/NewKeynesian\\_model\\_handout.pdf](http://faculty.wcas.northwestern.edu/~lchrist/course/China_Chengdu_2016/NewKeynesian_model_handout.pdf)
  - In RBC model, markets obtain socially efficient allocations independent of monetary policy.
  - In NK model, markets don't necessarily work well and good monetary policy essential.
- Solve the model.

# Summarizing the Equilibrium Conditions

- Break up the equilibrium conditions into three sets:
  - ❶ Conditions (1)-(4) for prices:  $K_t, F_t, \bar{\pi}_t, p_t^*, s_t$
  - ❷ Conditions (6)-(10) for:  $C_t, Y_t, N_t, I_t, \mu_t$
  - ❸ Conditions (5) and (11) for  $R_t$  and  $\chi_t$ .
- We have 11 equilibrium conditions for 12 variables: system is underdetermined.
  - Not surprising: have said nothing about monetary policy.

# Equilibrium Conditions Associated with Price Setting

$$K_t = \frac{\varepsilon}{\varepsilon - 1} \frac{Y_t}{C_t} s_t + \beta \theta E_t \bar{\pi}_{t+1}^\varepsilon K_{t+1} \quad (1)$$

$$F_t = \frac{Y_t}{C_t} + \beta \theta E_t \bar{\pi}_{t+1}^{\varepsilon-1} F_{t+1} \quad (2)$$

$$\frac{K_t}{F_t} = \left[ \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right]^{\frac{1}{1-\varepsilon}} \quad (3)$$

$$p_t^* = \left[ (1 - \theta) \left( \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right)^{\frac{\varepsilon}{\varepsilon-1}} + \frac{\theta \bar{\pi}_t^\varepsilon}{p_{t-1}^*} \right]^{-1} \quad (4)$$

# Equilibrium Conditions Associated With Gross Output

- Equations:

$$Y_t = p_t^* A_t N_t^\gamma I_t^{1-\gamma} \quad (6), \quad C_t + I_t = Y_t \quad (7), \quad I_t = \mu_t \frac{Y_t}{p_t^*} \quad (8)$$

$$s_t = (1 - \nu) (1 - \psi + \psi R_t) \left( \frac{1}{1 - \gamma} \right)^{1-\gamma} \times \left( \frac{1}{\gamma} \underbrace{\exp(\tau_t) C_t N_t^\varphi}_{\text{used household Euler equation to substitute out } W_t/P_t} \right)^\gamma \frac{1}{A_t}$$

$$\mu_t = \frac{(1 - \gamma) s_t}{(1 - \nu) (1 - \psi + \psi R_t)} \quad (10),$$

# Other Equilibrium Conditions

- Allocative distortion:

$$\chi_t = \left( p_t^* \left( \frac{1 - \frac{\mu_t}{p_t^*}}{\gamma} \right)^\gamma \left( \frac{\frac{\mu_t}{p_t^*}}{1 - \gamma} \right)^{1-\gamma} \right)^{\frac{1}{\gamma}} \quad (11)$$

- Intertemporal equation

$$\frac{1}{C_t} = \beta E_t \frac{1}{C_{t+1}} \frac{R_t}{\bar{\pi}_{t+1}} \quad (5)$$

- On way to close the system: specify a monetary policy rule:

$$R_t/R = (R_{t-1}/R)^\rho \exp [(1 - \rho) \phi_\pi (\bar{\pi}_t - \bar{\pi}) + u_t] \quad (12)$$

- Smoothing parameter:  $\rho$ .
  - Bigger is  $\rho$  the more persistent are policy-induced changes in the interest rate.
- Monetary policy shock:  $u_t$ .

# Conclusion About Networks

- Networks alter the New Keynesian model's implications for inflation.
  - Doubles the cost of inflation.
  - Phillips curve is flatter because of strategic complementarities (when there are price frictions, this makes materials prices inertial which makes marginal costs inertial, which reduces firms' interest in changing prices).
- For the result on the Taylor principle, see my 2011 handbook chapter and Christiano (2015).
  - When the smoothing parameter in Taylor rule is set to zero and  $\psi = 1$ , then the model has indeterminacy, even when the coefficient on inflation is 1.5.
  - So, the likelihood of the Taylor principle breaking down goes up when  $\gamma$  is reduced, consistent with intuition.
  - When the smoothing parameter is at its empirically plausible value of 0.8, then the solution of the model does not display indeterminacy.
