Information Criteria and Model Selection

Herman J. Bierens

August 27, 2004

1. Introduction

Let \( L_n(k) \) be the likelihood of a model with \( k \) parameters based on a sample of size \( n \), and let \( k_0 \) be the correct number of parameters. Suppose that for \( k > k_0 \) the model with \( k \) parameters is nested in the model with \( k_0 \) parameters, so that \( L_n(k_0) \) is obtained by setting \( k - k_0 \) parameters in the larger model to constants. The Akaike, Hannan-Quinn, and Schwarz information criteria for selecting the number of parameters are

- **Akaike:**
  \[
  c_n(k) = -2 \ln(L_n(k))/n + 2k/n,
  \]

- **Hannan-Quinn:**
  \[
  c_n(k) = -2 \ln(L_n(k))/n + 2k \ln(n)/n,
  \]

- **Schwarz:**
  \[
  c_n(k) = -2 \ln(L_n(k))/n + k \ln(n)/n,
  \]

respectively, i.e., \( k_0 \) can be estimated by

\[
\hat{k} = \arg\min_k c_n(k).
\]

2. Consistency

If \( k < k_0 \) then \( \lim_{n \to \infty} \ln(L_n(k))/n < \lim_{n \to \infty} \ln(L_n(k_0))/n \), hence in all three cases

\[
\lim_{n \to \infty} P[c_n(k_0) \geq c_n(k)] = 0.
\]

For \( k > k_0 \) it follows from the likelihood ratio test that

\[
2\left( \ln(L_n(k)) - \ln(L_n(k_0)) \right) \xrightarrow{d} \chi^2_{k-k_0},
\]

where \( \xrightarrow{d} \) indicates convergence in distribution. Then in the Akaike case,

\[
n_c(k_0) - c_n(k) = 2\left( \ln(L_n(k)) - \ln(L_n(k_0)) \right) - 2(k-k_0) \xrightarrow{d} \chi^2_{k-k_0} - 2(k-k_0),
\]

1
where $X_{k-k_0} \sim \chi^2_{k-k_0}$, hence
\[
\lim_{n \to \infty} P[c_n(k_0) > c_n(k)] = P[X_{k-k_0} > 2(k-k_0)] > 0.
\]

Therefore, the Akaike criterion may asymptotically overshoot the correct number of parameters. Since (1) implies
\[
\text{plim}_{n \to \infty} \frac{2 \{\ln(L_n(k)) - \ln(L_n(k_0))\}}{\ln(n)} = 0
\]
and
\[
\text{plim}_{n \to \infty} \frac{2 \{\ln(L_n(k)) - \ln(L_n(k_0))\}}{\ln(n)} = 0
\]
it follows that in the Hannan-Quinn case,
\[
\text{plim}_{n \to \infty} \frac{n(c_n(k_0) - c_n(k))}{\ln(n)} = 2(k-k_0) \geq 2
\]
and in the Schwarz case,
\[
\text{plim}_{n \to \infty} \frac{n(c_n(k_0) - c_n(k))}{\ln(n)} = k-k_0 \geq 1,
\]
so that in both cases
\[
\lim_{n \to \infty} P[c_n(k_0) > c_n(k)] = 0.
\]
Consequently, in the Akaike case we have
\[
\lim_{n \to \infty} P[\hat{k} \geq k_0] = 1, \text{ but } \lim_{n \to \infty} P[\hat{k} > k_0] > 0,
\]
whereas in the Hannan-Quinn and Schwarz cases,
\[
\lim_{n \to \infty} P[\hat{k} = k_0] = 1.
\]

If the model with $k > k_0$ is not nested in the correct model with $k_0$ parameters, then $L_n(k)$ is the quasi-likelihood of a misspecified model. Hence, similarly to the case $k < k_0$ we then have
\[
\text{plim}_{n \to \infty} \frac{\ln(L_n(k))}{n} < \text{plim}_{n \to \infty} \frac{\ln(L_n(k_0))}{n},
\]
so that all three information criteria will asymptotically detect this case. Consequently, these information criteria can also be used for model selection in the
case that the explanatory variables do not have a natural ordering, but again only the Hannan-Quinn and Schwarz criteria will asymptotically yield the correct model.

3. Applications

3.1 VAR and AR model selection

If $L_n(k)$ is the likelihood of a Gaussian VAR($p$) model,

$$
Y_t = a_0 + \sum_{j=1}^{p} A_j Y_{t-j} + U_t, \quad U_t \sim i.i.d. N_m[0, \Sigma],
$$

where $Y_t \in \mathbb{R}^m$ is observed for $t = 1, \ldots, n$, then $k = m + m^2 p$ and

$$
\ln(L_n(k)) = -\frac{1}{2}n.m - \frac{1}{2}n.\ln[\det(\hat{\Sigma}_p)],
$$

where $\hat{\Sigma}_p$ is the maximum likelihood estimator of the error variance $\Sigma$. Then we may use these criteria to determine the order $p$ of the VAR:

$$
\hat{p} = \arg\min_p c_n^{VAR}(p),
$$

where

Akaike: $c_n^{VAR}(p) = \ln(\det(\hat{\Sigma}_p)) + 2(m+m^2 p)/n,$

Hannan-Quinn: $c_n^{VAR}(p) = \ln(\det(\hat{\Sigma}_p)) + 2(m+m^2 p)\ln(\ln(n))/n,$

Schwarz: $c_n^{VAR}(p) = \ln(\det(\hat{\Sigma}_p)) + (m+m^2 p)\ln(n)/n.$

These criteria can also be used to determine the order of an AR($p$) model

$$
Y_t = a_0 + \sum_{j=1}^{p} a_j Y_{t-j} + U_t, \quad U_t \sim i.i.d. N[0, \sigma^2],
$$

where again $Y_t \in \mathbb{R}$ is observed for $t = 1, \ldots, n$, simply by replacing $m$ with $1$ and $\det(\hat{\Sigma}_p)$ with the ML estimator $\hat{\sigma}^2_p$ of the error variance $\sigma^2$:

Akaike: $c_n^{AR}(p) = \ln(\hat{\sigma}^2_p) + 2(1+p)/n,$
Hannan-Quinn:  \[ c_n^{AR}(p) = \ln(\hat{\sigma}_p^2) + 2(1+p)\ln(\ln(n))/n, \]
Schwarz:  \[ c_n^{AR}(p) = \ln(\hat{\sigma}_p^2) + (1+p)\ln(n)/n. \]

### 3.2 ARMA model specification

Similarly, in the ARMA\((p,q)\) case

\[ Y_t = \alpha_0 + \sum_{j=1}^p \alpha_j Y_{t-j} + U_t - \sum_{j=1}^q \beta_j U_{t-j}, \]
\[ U_t \sim i.i.d. \mathcal{N}[0,\hat{\sigma}_{p,q}^2], \]

these criteria become

Akaike:  \[ c_n^{ARMA}(p,q) = \ln(\hat{\sigma}_{p,q}^2) + 2(1+p+q)/n, \]
Hannan-Quinn:  \[ c_n^{ARMA}(p,q) = \ln(\hat{\sigma}_{p,q}^2) + 2(1+p+q)\ln(\ln(n))/n, \]
Schwarz:  \[ c_n^{ARMA}(p,q) = \ln(\hat{\sigma}_{p,q}^2) + (1+p+q)\ln(n)/n, \]

where now \( \hat{\sigma}_{p,q}^2 \) is the ML estimator of the error variance \( \sigma^2 \) and \( n \) is the number of observations used in the ML estimation.

### 4. Designing your own model selection criterion

Consider a collection of \( M \) models indexed by \( m = 1,\ldots,M \), where each model is characterized by a parameter vector \( \theta_m \) of dimension \( k_m \) in a parameter space \( \Theta_m \subset \mathbb{R}^{k_m} \). A correct model, correct in the sense that it has all the properties that it supposed to have, should be among these models. The parameters in each model are estimated by minimizing an objective function \( Q_{m,n}(\theta_m) \), where \( n \) is the number of observations. Thus, each \( \theta_m \) is estimated by

\[ \hat{\theta}_{m,n} = \arg\min_{\theta_m} Q_{m,n}(\theta). \]

It is possible to set forth regularity conditions such that \( \lim_{n\to\infty} Q_{m,n}(\theta_m) = \mathcal{Q}_m(\theta_m) \) exists and is finite, and denote

\[ \hat{\theta}_m = \arg\min_{\theta_m} \mathcal{Q}_m(\theta). \]

This is the pseudo-true value of the parameter vector of model \( m \). Moreover, it is possible to set forth
further regularity conditions such that
\[ \text{plim}_{n \to \infty} Q_{m,n}(\theta_{m,n}) = \overline{Q}_m(\theta_m^0). \]

Now divide this collection of models into two groups. Let the first group contain all the models that are correctly specified but possibly over-parametrized, say the models \( m = 1, \ldots, K < M \). Without loss of generality we may assume that model \( m = 1 \) is the most parsimonious of the models in this group, i.e., \( k_1 < k_m \) for \( m = 2, \ldots, K \), and that model 1 is nested in the other models in this group, so that
\[ \overline{Q}_1(\theta_1^0) = \overline{Q}_m(\theta_m^0) \text{ for } m = 2, \ldots, K. \]
The other group of models, for \( m = K+1, \ldots, M \), consists of models that are misspecified, so that
\[ \overline{Q}_1(\theta_1^0) < \overline{Q}_m(\theta_m^0) \text{ for } m = K+1, \ldots, M. \]
The customized model selection criterion then takes the form
\[ c_n(m) = Q_{m,n}(\theta_{m,n}) + \rho(k_m,n) \]
where \( \rho(k_m,n) \) is a penalty function satisfying \( \lim_{n \to \infty} \rho(k_m,n) = 0 \) for \( m = 1, \ldots, M \). For \( m = K+1, \ldots, M \), we have \( \text{plim}_{n \to \infty}(c_n(m) - c_n(1)) = \overline{Q}_m(\theta_m^0) - \overline{Q}_1(\theta_1^0) > 0 \) and thus
\[ \lim_{n \to \infty} P[c_n(m) > c_n(1)] = 1 \text{ for } m = K+1, \ldots, M. \]
In order to select the most parsimonious model from the set of (over-parametrized) correct models, we need a further condition on the penalty \( \rho(k_m,n) \). This further condition depends on the rate \( \beta_n \) of convergence in distribution of \( \beta_n(Q_{1,n}(\theta_{1,n}) - Q_{m,n}(\theta_{m,n})) \) for \( m = 2, \ldots, K \). In the log-likelihood case \( \beta_n = n \), i.e., if \( -n.Q_{m,n}(\theta_{m,n}) \) is two-times a log-likelihood then we have seen above that
\[ n[Q_{1,n}(\theta_{1,n}) - Q_{m,n}(\theta_{m,n})] \overset{d}{\to} \chi^2_{k_m-k_1}. \]
Let \( \alpha_n \) be a sequence of positive numbers converging to infinity such that \( \alpha_n / \beta_n \to 0 \). Then
\[ \text{plim}_{n \to \infty} \alpha_n [Q_{1,n}(\theta_{1,n}) - Q_{m,n}(\theta_{m,n})] = 0 \text{ for } m = 2, \ldots, K. \]
Next, specify the penalty function \( \rho(k_m,n) \) such that
\[
\lim_{n \to \infty} \alpha_n \rho(k_m, n) = \bar{\rho}(k_m),
\]

where \(\bar{\rho}(k)\) is increasing in \(k\). For example, let \(\rho(k, n) = k/a_n\). Then \(\lim_{n \to \infty} a_n (c_n(m) - c_n(1)) = \bar{\rho}(k_m) - \bar{\rho}(k_1) > 0\), so that

\[
\lim_{n \to \infty} P[c_n(m) > c_n(1)] = 1 \quad \text{for} \quad m = 2, \ldots, K.
\]

Consequently, choosing the model according to

\[
\hat{m} = \arg\min_{m=1,\ldots,M} c_n(m)
\]

will asymptotically yield the most parsimonious correct model, i.e., if model 1 is this model then

\[
\lim_{n \to \infty} P[\hat{m} = 1] = 1.
\]
