Homework 2.
Due: Monday, May 22.

1. Consider the nonstochastic version of the Clarida-Gali-Gertler model. The pricing equation, the household’s Euler equation and the Taylor rule are as follows:

\[
\begin{align*}
\delta \pi_{t+1} + \lambda y_t - \pi_t &= 0 \\
y_{t+1} - y_t - \frac{1}{\sigma}(r_t - \pi_{t+1}) &= 0 \\
\rho r_{t-1} + (1 - \rho)\beta \pi_{t+1} + (1 - \rho)\gamma y_t - r_t &= 0.
\end{align*}
\]

For a detailed rationale of these equations, see class notes, the CGG paper and (especially for the price equation), Woodford (1996) (the latter two papers are on the class web site). Write this system in the form:

\[AY_{t+1} + BY_t = 0,\]

for \( t = 1, \ldots \) (note: in class the initial period is \( t = 0 \), but here I have changed it to \( t = 1 \)). Here, \( Y_t = (\pi_t, y_t, r_{t-1}) \). Use the following parameter values, \( \delta = 0.99, \sigma = 1, \lambda = 0.3, \gamma = 1, \rho = 0.5, \beta = 0.966 \). Let the initial interest rate, \( r_0 \), have its steady state value of 0.

1. Compute \( P \) and \( \Lambda \) in the eigenvector, eigenvalue decomposition of \(-A^{-1}B\).

2. Compute the set of minimal state variable solutions (i.e., the set of \( 2 \times 3 \) matrices with the property \( DY_1 = 0 \implies DY_t = 0 \) for all \( t \)).

3. Suppose the first period is \( t = 1 \), and time evolves for \( t = 1, 2, 3, \ldots, 20 \). Construct the following 3 graphs. In each graph, display two lines of length 20 each, with \( t = 1, \ldots, 20 \) on the horizontal axis. One line, a line of zeros, corresponds to the nonstochastic, steady state equilibrium of the model. The other is a convergent solution to the Euler equations in which \( \pi_1 \) is a little greater than zero. Note how the high inflation equilibrium, while eventually returning to steady state, displays a period of high inflation and high output.
2. Now, construct a sunspot equilibrium for the model. To do this, note that in the stochastic version of the model, the equations are satisfied after application of the $E_t$ operator. Write the state-space representation of the model,

$$AY_{t+1} + BY_t = \omega_{t+1},$$

where $\omega_{t+1}$ is an arbitrary random variable with $E_t \omega_{t+1} = 0$ for all $t$. Identify a convergent solution to this model in which $\omega_t$ is a non-trivial random variable. Draw $\omega_t$ from a random number generator in MATLAB and simulate the response of the three variables in $Y_t$ to the sunspot. Graph this like in 1 above. Also, display a simulation of the response of the system in a sunspot solution that does not display convergence.
