# Solving Dynamic General Equilibrium Models Using Log Linear Approximation

# Log-linearization strategy

---

- Example #1: A Simple RBC Model.
  - Define a Model ‘Solution’
  - Motivate the Need to Somehow Approximate Model Solutions
  - Describe Basic Idea Behind Log Linear Approximations
  - Some Strange Examples to be Prepared For
    - ‘Blanchard-Kahn conditions not satisfied’
- Example #2: Putting the Stochastic RBC Model into General Canonical Form
- Example #3: Stochastic RBC Model with Hours Worked (Matrix Generalization of Previous Results)
- Example #4: Example #3 with ‘Exotic’ Information Sets.
- Summary so Far.
- Example #5: Sticky price model with no capital - log linearizing about a particular benchmark.
  - Will exploit the example to derive the nonlinear equilibrium conditions of a New Keynesian model (will be used later in discussions of optimal policy).

# Example #1: Nonstochastic RBC Model

---

$$\text{Maximize}_{\{c_t, K_{t+1}\}} \sum_{t=0}^{\infty} \beta^t \frac{C_t^{1-\sigma}}{1-\sigma},$$

subject to:

$$C_t + K_{t+1} - (1 - \delta)K_t = K_t^\alpha, K_0 \text{ given}$$

First order condition:

$$C_t^{-\sigma} - \beta C_{t+1}^{-\sigma} [\alpha K_{t+1}^{\alpha-1} + (1 - \delta)],$$

or, after substituting out resource constraint:

$$v(K_t, K_{t+1}, K_{t+2}) = 0, t = 0, 1, \dots, \text{ with } K_0 \text{ given.}$$

## Example #1: Nonstochastic RBC Model ...

- ‘Solution’: a function,  $K_{t+1} = g(K_t)$ , such that

$$v(K_t, g(K_t), g[g(K_t)]) = 0, \text{ for all } K_t.$$

- Problem:

This is an Infinite Number of Equations  
(one for each possible  $K_t$ )  
in an Infinite Number of Unknowns  
(a value for  $g$  for each possible  $K_t$ )

- With Only a Few Rare Exceptions this is Very Hard to Solve Exactly
  - Easy cases:
    - \* If  $\sigma = 1, \delta = 1 \Rightarrow g(K_t) = \alpha\beta K_t^\alpha$ .
    - \* If  $v$  is linear in  $K_t, K_{t+1}, K_{t+1}$ .
  - Standard Approach: Approximate  $v$  by a Log Linear Function.

# Approximation Method Based on Linearization

---

- Three Steps
  - Compute the Steady State
  - Do a Log Linear Expansion About Steady State
  - Solve the Resulting Log Linearized System
- Step 1: Compute Steady State -
  - Steady State Value of  $K$ ,  $K^*$  -

$$\begin{aligned}C^{-\sigma} - \beta C^{-\sigma} [\alpha K^{\alpha-1} + (1 - \delta)] &= 0, \\ \Rightarrow \alpha K^{\alpha-1} + (1 - \delta) &= \frac{1}{\beta} \\ \Rightarrow K^* &= \left[ \frac{\alpha}{\frac{1}{\beta} - (1 - \delta)} \right]^{\frac{1}{1-\alpha}}.\end{aligned}$$

- $K^*$  satisfies:

$$v(K^*, K^*, K^*) = 0.$$

## Approximation Method Based on Linearization ...

- Step 2:

- Replace  $v$  by First Order Taylor Series Expansion About Steady State:

$$v_1(K_t - K^*) + v_2(K_{t+1} - K^*) + v_3(K_{t+2} - K^*) = 0,$$

- Here,

$$v_1 = \frac{dv_u(K_t, K_{t+1}, K_{t+2})}{dK_t}, \text{ at } K_t = K_{t+1} = K_{t+2} = K^*.$$

- Conventionally, do *Log-Linear Approximation*:

$$(v_1K) \hat{K}_t + (v_2K) \hat{K}_{t+1} + (v_3K) \hat{K}_{t+2} = 0,$$
$$\hat{K}_t \equiv \frac{K_t - K^*}{K^*}.$$

- Write this as:

$$\alpha_2 \hat{K}_t + \alpha_1 \hat{K}_{t+1} + \alpha_0 \hat{K}_{t+2} = 0,$$
$$\alpha_2 = v_1K, \alpha_1 = v_2K, \alpha_0 = v_3K$$

## Approximation Method Based on Linearization ...

- Step 3: Solve

- Posit the Following Policy Rule:

$$\hat{K}_{t+1} = A\hat{K}_t,$$

Where  $A$  is to be Determined.

- Compute  $A$  :

$$\alpha_2\hat{K}_t + \alpha_1A\hat{K}_t + \alpha_0A^2\hat{K}_t = 0,$$

or

$$\alpha_2 + \alpha_1A + \alpha_0A^2 = 0.$$

- $A$  is the Eigenvalue of Polynomial

- In General: Two Eigenvalues.

- Can Show: In RBC Example, One Eigenvalue is Explosive. The Other Not.
- There Exist Theorems (see Stokey-Lucas, chap. 6) That Say You Should Ignore the Explosive  $A$ .

# Some Strange Examples to be Prepared For

---

- Other Examples Are Possible:
  - Both Eigenvalues Explosive
  - Both Eigenvalues Non-Explosive
  - What Do These Things Mean?

## Some Strange Examples to be Prepared For ...

- Example With Two Explosive Eigenvalues
- Preferences:

$$\sum_{t=0}^{\infty} \beta^t \frac{C_t^\gamma}{\gamma}, \quad \gamma < 1.$$

- Technology:
  - Production of Consumption Goods

$$C_t = k_t^\alpha n_t^{1-\alpha}$$

- Production of Capital Goods

$$k_{t+1} = 1 - n_t.$$

## Some Strange Examples to be Prepared For ...

- Planning Problem:

$$\max \sum_{t=0}^{\infty} \beta^t \frac{\left[ k_t^\alpha (1 - k_{t+1})^{1-\alpha} \right]^\gamma}{\gamma}$$

- Euler Equation:

$$\begin{aligned} v(k_t, k_{t+1}, k_{t+2}) &= -(1 - \alpha)k_t^{\alpha\gamma}(1 - k_{t+1})^{[(1-\alpha)\gamma-1]} + \beta\alpha k_{t+1}^{(\alpha\gamma-1)}(1 - k_{t+2})^{(1-\alpha)\gamma} \\ &= 0, \end{aligned}$$

$$t = 0, 1, \dots$$

- Steady State:

$$k = \frac{\alpha\beta}{1 - \alpha + \alpha\beta}.$$

## Some Strange Examples to be Prepared For ...

- Log-linearize Euler Equation:

$$\alpha_0 \hat{k}_{t+2} + \alpha_1 \hat{k}_{t+1} + \alpha_2 \hat{k}_t = 0$$

- With  $\beta = 0.58$ ,  $\gamma = 0.99$ ,  $\alpha = 0.6$ , *Both* Roots of Euler Equation are explosive:

$$-1.6734, \quad -1.0303$$

- Other Properties:
  - Steady State:

$$0.4652$$

- Two-Period Cycle:

$$0.8882, \quad 0.0870$$

## Some Strange Examples to be Prepared For ...

- Meaning of Stokey-Lucas Example
  - Illustrates the Possibility of All Explosive Roots
  - Economics:
    - \* If Somehow You Start At Single Steady State, Stay There
    - \* If You are Away from Single Steady State, Go Somewhere Else
  - If Log Linearized Euler Equation Around Particular Steady State Has Only Explosive Roots
    - \* All Possible Equilibria Involve Leaving that Steady State
    - \* Log Linear Approximation Not Useful, Since it Ceases to be Valid Outside a Neighborhood of Steady State
  - Could Log Linearize About Two-Period Cycle (That's Another Story...)
  - The Example Suggests That *Maybe* All Explosive Root Case is Unlikely
  - 'Blanchard-Kahn conditions not satisfied, too many explosive roots'

## Some Strange Examples to be Prepared For ...

- Another Possibility:
  - Both Roots Stable
  - Many Paths Converge Into Steady State: Multiple Equilibria
  - Can Happen For Many Reasons
    - \* Strategic Complementarities Among Different Agents In Private Economy
    - \* Certain Types of Government Policy
  - This is a More Likely Possibility
  - Avoid Being Surprised by It By Always Thinking Through Economics of Model.

## Some Strange Examples to be Prepared For ...

- Strategic Complementarities Between Agent A and Agent B

- Payoff to agent A is higher if agent B is working harder

- In following setup, strategic complementarities give rise to two equilibria:

Me	Everyone else	
	work hard	take it easy
work hard	3	0
take it easy	1	1

- Example closer to home: every firm in the economy has a ‘pet investment project’ which only seems profitable if the economy is booming

- \* Equilibrium #1: each firm conjectures all other firms will invest, this implies a booming economy, so it makes sense for each firm to invest.

- \* Equilibrium #2: each firm conjectures all other firms will not invest, so economy will stagnate and it makes sense for each firm not to invest.

## Some Strange Examples to be Prepared For ...

– Example even closer to home:

\* firm production function -

$$y_t = A_t K_t^\alpha h_t^{1-\alpha},$$

$$A_t = Y_t^\gamma, Y_t \sim \text{economy-wide average output}$$

\* resource constraint -

$$C_t + K_{t+1} - (1 - \delta) K_t = Y_t$$

\* equilibrium condition -

$Y_t = y_t$  ‘economy-wide average output is average of individual firms’ production’

\* household preferences -

$$\sum_{t=0}^{\infty} \beta^t u(C_t, h_t)$$

\*  $\gamma$  large enough leads to two stable eigenvalues, multiple equilibria.

## Some Strange Examples to be Prepared For ...

- Lack of Commitment in Government Policy Can Lead to Multiple Equilibria
  - Simple economy: households solve

$$\max u(c, h) = c - \frac{1}{2}l^2$$

$$c \leq (1 - \tau)wh,$$

$w$  is technologically determined marginal product of labor.

- Government chooses  $\tau$  to satisfy its budget constraint

$$g \leq \tau wl$$

## Some Strange Examples to be Prepared For ...

### – Laffer curve

- Two scenarios depending on ‘order of moves’
  - \* commitment: (i) government sets  $\tau$  (ii) private economy acts
    - lowest possible  $\tau$  only possible outcome
  - \* no commitment: (i) private economy determines  $h$  (ii) government chooses  $\tau$ 
    - at least two possible equilibria - lowest possible  $\tau$  or high  $\tau$
- For an environment like this that leads to too many stable eigenvalues, see Schmitt-Grohe and Uribe paper on balanced budget, *JPE*.

## Example #2: RBC Model With Uncertainty

---

- Model

$$\text{Maximize } E_0 \sum_{t=0}^{\infty} \beta^t \frac{C_t^{1-\sigma}}{1-\sigma},$$

subject to

$$C_t + K_{t+1} - (1 - \delta)K_t = K_t^\alpha \varepsilon_t,$$

where  $\varepsilon_t$  is a stochastic process with  $E\varepsilon_t = \varepsilon$ , say. Let

$$\hat{\varepsilon}_t = \frac{\varepsilon_t - \varepsilon}{\varepsilon},$$

and suppose

$$\hat{\varepsilon}_t = \rho \hat{\varepsilon}_{t-1} + e_t, \quad e_t \sim N(0, \sigma_e^2).$$

- First Order Condition:

$$E_t \left\{ C_t^{-\sigma} - \beta C_{t+1}^{-\sigma} [\alpha K_{t+1}^{\alpha-1} \varepsilon_{t+1} + 1 - \delta] \right\} = 0.$$

## Example #2: RBC Model With Uncertainty ...

- First Order Condition:

$$E_t v(K_{t+2}, K_{t+1}, K_t, \varepsilon_{t+1}, \varepsilon_t) = 0,$$

where

$$\begin{aligned} & v(K_{t+2}, K_{t+1}, K_t, \varepsilon_{t+1}, \varepsilon_t) \\ &= (K_t^\alpha \varepsilon_t + (1 - \delta)K_t - K_{t+1})^{-\sigma} \\ &\quad - \beta (K_{t+1}^\alpha \varepsilon_{t+1} + (1 - \delta)K_{t+1} - K_{t+2})^{-\sigma} \\ &\quad \times [\alpha K_{t+1}^{\alpha-1} \varepsilon_{t+1} + 1 - \delta]. \end{aligned}$$

- Solution: a  $g(K_t, \varepsilon_t)$ , Such That

$$E_t v(g(g(K_t, \varepsilon_t), \varepsilon_{t+1}), g(K_t, \varepsilon_t), K_t, \varepsilon_{t+1}, \varepsilon_t) = 0,$$

For All  $K_t, \varepsilon_t$ .

- Hard to Find  $g$ , Except in Special Cases
  - One Special Case:  $v$  is Log Linear.

## Example #2: RBC Model With Uncertainty ...

- Log Linearization Strategy:
  - Step 1: Compute Steady State of  $K_t$  when  $\varepsilon_t$  is Replaced by  $E\varepsilon_t$
  - Step2: Replace  $v$  By its Taylor Series Expansion About Steady State.
  - Step 3: Solve Resulting Log Linearized System.
- Logic: If Actual Stochastic System Remains in a Neighborhood of Steady State, Log Linear Approximation Good

## Example #2: RBC Model With Uncertainty ...

- Caveat: Strategy not accurate in all conceivable situations.
  - Example: suppose that where I live -

$$\varepsilon \equiv \text{temperature} = \begin{cases} 140 \text{ Fahrenheit, 50 percent of time} \\ 0 \text{ degrees Fahrenheit the other half} \end{cases} .$$

- On average, temperature quite nice:  $E\varepsilon = 70$  (like parts of California)
- Let  $K$  = capital invested in heating and airconditioning
  - \*  $EK$  very, very large!
  - \* Economist who predicts investment based on replacing  $\varepsilon$  by  $E\varepsilon$  would predict  $K = 0$  (as in many parts of California)
- In standard model this is not a big problem, because shocks are not so big....steady state value of  $K$  (i.e., the value that results eventually when  $\varepsilon$  is replaced by  $E\varepsilon$ ) is approximately  $E\varepsilon$  (i.e., the average value of  $K$  when  $\varepsilon$  is stochastic).

## Example #2: RBC Model With Uncertainty ...

- Step 1: Steady State:

$$K^* = \left[ \frac{\alpha \varepsilon}{\frac{1}{\beta} - (1 - \delta)} \right]^{\frac{1}{1-\alpha}} .$$

- Step 2: Log Linearize -

$$\begin{aligned} & v(K_{t+2}, K_{t+1}, K_t, \varepsilon_{t+1}, \varepsilon_t) \\ & \simeq v_1 (K_{t+2} - K^*) + v_2 (K_{t+1} - K^*) + v_3 (K_t - K^*) \\ & \quad + v_3 (\varepsilon_{t+1} - \varepsilon) + v_4 (\varepsilon_t - \varepsilon) \\ & = v_1 K^* \left( \frac{K_{t+2} - K^*}{K^*} \right) + v_2 K^* \left( \frac{K_{t+1} - K^*}{K^*} \right) + v_3 K^* \left( \frac{K_t - K^*}{K^*} \right) \\ & \quad + v_3 \varepsilon \left( \frac{\varepsilon_{t+1} - \varepsilon}{\varepsilon} \right) + v_4 \varepsilon \left( \frac{\varepsilon_t - \varepsilon}{\varepsilon} \right) \\ & = \alpha_0 \hat{K}_{t+2} + \alpha_1 \hat{K}_{t+1} + \alpha_2 \hat{K}_t + \beta_0 \hat{\varepsilon}_{t+1} + \beta_1 \hat{\varepsilon}_t . \end{aligned}$$

## Example #2: RBC Model With Uncertainty ...

- Step 3: Solve Log Linearized System

- Posit:

$$\hat{K}_{t+1} = A\hat{K}_t + B\hat{\varepsilon}_t.$$

- Pin Down  $A$  and  $B$  By Condition that log-linearized Euler Equation Must Be Satisfied.

- \* Note:

$$\begin{aligned}\hat{K}_{t+2} &= A\hat{K}_{t+1} + B\hat{\varepsilon}_{t+1} \\ &= A^2\hat{K}_t + AB\hat{\varepsilon}_t + B\rho\hat{\varepsilon}_t + Be_{t+1}.\end{aligned}$$

- \* Substitute Posited Policy Rule into Log Linearized Euler Equation:

$$E_t \left[ \alpha_0 \hat{K}_{t+2} + \alpha_1 \hat{K}_{t+1} + \alpha_2 \hat{K}_t + \beta_0 \hat{\varepsilon}_{t+1} + \beta_1 \hat{\varepsilon}_t \right] = 0,$$

so must have:

$$\begin{aligned}E_t \{ \alpha_0 [ A^2 \hat{K}_t + AB\hat{\varepsilon}_t + B\rho\hat{\varepsilon}_t + Be_{t+1} ] \\ + \alpha_1 [ A\hat{K}_t + B\hat{\varepsilon}_t ] + \alpha_2 \hat{K}_t + \beta_0 \rho \hat{\varepsilon}_t + \beta_0 e_{t+1} + \beta_1 \hat{\varepsilon}_t \} = 0\end{aligned}$$

## Example #2: RBC Model With Uncertainty ...

\* Then,

$$\begin{aligned}
 E_t \left[ \alpha_0 \hat{K}_{t+2} + \alpha_1 \hat{K}_{t+1} + \alpha_2 \hat{K}_t + \beta_0 \hat{\varepsilon}_{t+1} + \beta_1 \hat{\varepsilon}_t \right] \\
 &= E_t \left\{ \alpha_0 \left[ A^2 \hat{K}_t + AB \hat{\varepsilon}_t + B \rho \hat{\varepsilon}_t + B e_{t+1} \right] \right. \\
 &+ \alpha_1 \left[ A \hat{K}_t + B \hat{\varepsilon}_t \right] + \alpha_2 \hat{K}_t + \beta_0 \rho \hat{\varepsilon}_t + \beta_0 e_{t+1} + \beta_1 \hat{\varepsilon}_t \left. \right\} \\
 &= \alpha(A) \hat{K}_t + F \hat{\varepsilon}_t \\
 &= 0
 \end{aligned}$$

where

$$\begin{aligned}
 \alpha(A) &= \alpha_0 A^2 + \alpha_1 A + \alpha_2, \\
 F &= \alpha_0 AB + \alpha_0 B \rho + \alpha_1 B + \beta_0 \rho + \beta_1
 \end{aligned}$$

\* Find  $A$  and  $B$  that Satisfy:

$$\alpha(A) = 0, F = 0.$$

# Example #3 RBC Model With Hours Worked and Uncertainty

---

- Maximize

$$E_t \sum_{t=0}^{\infty} \beta^t U(C_t, N_t)$$

subject to

$$C_t + K_{t+1} - (1 - \delta)K_t = f(K_t, N_t, \varepsilon_t)$$

and

$$E\varepsilon_t = \varepsilon,$$

$$\hat{\varepsilon}_t = \rho\hat{\varepsilon}_{t-1} + e_t, e_t \sim N(0, \sigma_e^2)$$

$$\hat{\varepsilon}_t = \frac{\varepsilon_t - \varepsilon}{\varepsilon}.$$

### Example #3 RBC Model With Hours Worked and Uncertainty ...

- First Order Conditions:

$$E_t v_K(K_{t+2}, N_{t+1}, K_{t+1}, N_t, K_t, \varepsilon_{t+1}, \varepsilon_t) = 0$$

and

$$v_N(K_{t+1}, N_t, K_t, \varepsilon_t) = 0.$$

where

$$\begin{aligned} & v_K(K_{t+2}, N_{t+1}, K_{t+1}, N_t, K_t, \varepsilon_{t+1}, \varepsilon_t) \\ = & U_c(f(K_t, N_t, \varepsilon_t) + (1 - \delta)K_t - K_{t+1}, N_t) \\ & - \beta U_c(f(K_{t+1}, N_{t+1}, \varepsilon_{t+1}) + (1 - \delta)K_{t+1} - K_{t+2}, N_{t+1}) \\ & \times [f_K(K_{t+1}, N_{t+1}, \varepsilon_{t+1}) + 1 - \delta] \end{aligned}$$

and,

$$\begin{aligned} & v_N(K_{t+1}, N_t, K_t, \varepsilon_t) \\ = & U_N(f(K_t, N_t, \varepsilon_t) + (1 - \delta)K_t - K_{t+1}, N_t) \\ & + U_c(f(K_t, N_t, \varepsilon_t) + (1 - \delta)K_t - K_{t+1}, N_t) \\ & \times f_N(K_t, N_t, \varepsilon_t). \end{aligned}$$

- Steady state  $K^*$  and  $N^*$  such that Equilibrium Conditions Hold with  $\varepsilon_t \equiv \varepsilon$ .

### Example #3 RBC Model With Hours Worked and Uncertainty ...

- Log-Linearize the Equilibrium Conditions:

$$\begin{aligned} & v_K(K_{t+2}, N_{t+1}, K_{t+1}, N_t, K_t, \varepsilon_{t+1}, \varepsilon_t) \\ &= v_{K,1}K^* \hat{K}_{t+2} + v_{K,2}N^* \hat{N}_{t+1} + v_{K,3}K^* \hat{K}_{t+1} + v_{K,4}N^* \hat{N}_t + v_{K,5}K^* \hat{K}_t \\ & \quad + v_{K,6}\varepsilon \hat{\varepsilon}_{t+1} + v_{K,7}\varepsilon \hat{\varepsilon}_t \end{aligned}$$

$v_{K,j} \sim$  Derivative of  $v_K$  with respect to  $j^{th}$  argument, evaluated in steady state.

$$\begin{aligned} & v_N(K_{t+1}, N_t, K_t, \varepsilon_t) \\ &= v_{N,1}K^* \hat{K}_{t+1} + v_{N,2}N^* \hat{N}_t + v_{N,3}K^* \hat{K}_t + v_{N,4}\varepsilon \hat{\varepsilon}_{t+1} \end{aligned}$$

$v_{N,j} \sim$  Derivative of  $v_N$  with respect to  $j^{th}$  argument, evaluated in steady state.

### Example #3 RBC Model With Hours Worked and Uncertainty ...

- Representation Log-linearized Equilibrium Conditions

– Let

$$z_t = \begin{pmatrix} \hat{K}_{t+1} \\ \hat{N}_t \end{pmatrix}, \quad s_t = \hat{\varepsilon}_t, \quad \epsilon_t = e_t.$$

– Then, the linearized Euler equation is:

$$E_t [\alpha_0 z_{t+1} + \alpha_1 z_t + \alpha_2 z_{t-1} + \beta_0 s_{t+1} + \beta_1 s_t] = 0,$$

$$s_t = P s_{t-1} + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_e^2), \quad P = \rho.$$

– Here,

$$\alpha_0 = \begin{bmatrix} v_{K,1} K^* & v_{K,2} N^* \\ 0 & 0 \end{bmatrix}, \quad \alpha_1 = \begin{bmatrix} v_{K,3} K^* & v_{K,4} N^* \\ v_{N,1} K^* & v_{N,2} N^* \end{bmatrix},$$

$$\alpha_2 = \begin{bmatrix} v_{K,5} K^* & 0 \\ v_{N,3} K^* & 0 \end{bmatrix},$$

$$\beta_0 = \begin{pmatrix} v_{K,6} \varepsilon \\ 0 \end{pmatrix}, \quad \beta_1 = \begin{pmatrix} v_{K,7} \varepsilon \\ v_{N,4} \varepsilon \end{pmatrix}.$$

- Previous is a Canonical Representation That Essentially All Log Linearized Models Can be Fit Into (See Christiano (2002).)

### Example #3 RBC Model With Hours Worked and Uncertainty ...

- Again, Look for Solution

$$z_t = Az_{t-1} + Bs_t,$$

where  $A$  and  $B$  are pinned down by log-linearized Equilibrium Conditions.

- Now,  $A$  is *Matrix* Eigenvalue of *Matrix* Polynomial:

$$\alpha(A) = \alpha_0 A^2 + \alpha_1 A + \alpha_2 I = 0.$$

- Also,  $B$  Satisfies Same System of Log Linear Equations as Before:

$$F = (\beta_0 + \alpha_0 B)P + [\beta_1 + (\alpha_0 A + \alpha_1)B] = 0.$$

- Go for the 2 Free Elements of  $B$  Using 2 Equations Given by

$$F = \begin{bmatrix} 0 \\ 0 \end{bmatrix}.$$

### Example #3 RBC Model With Hours Worked and Uncertainty ...

- Finding the Matrix Eigenvalue of the Polynomial Equation,

$$\alpha(A) = 0,$$

and Determining if  $A$  is Unique is a Solved Problem.

- See Anderson, Gary S. and George Moore, 1985, 'A Linear Algebraic Procedure for Solving Linear Perfect Foresight Models,' *Economic Letters*, 17, 247-52 or Articles in *Computational Economics*, October, 2002. See also, the program, DYNARE.

### Example #3 RBC Model With Hours Worked and Uncertainty ...

- Solving for  $B$

- Given  $A$ , Solve for  $B$  Using Following (Log Linear) System of Equations:

$$F = (\beta_0 + \alpha_0 B)P + [\beta_1 + (\alpha_0 A + \alpha_1)B] = 0$$

- To See this, Use

$$\text{vec}(A_1 A_2 A_3) = (A_3' \otimes A_1) \text{vec}(A_2),$$

to Convert  $F = 0$  Into

$$\text{vec}(F') = d + q\delta = 0, \quad \delta = \text{vec}(B').$$

- Find  $B$  By First Solving:

$$\delta = -q^{-1}d.$$

## Example #4: Example #3 With ‘Exotic’ Information Set

---

- Suppose the Date  $t$  Investment Decision is Made Before the Current Realization of the Technology Shock, While the Hours Decision is Made Afterward.
- Now, Canonical Form Must Be Written Differently:

$$\mathcal{E}_t [\alpha_0 z_{t+1} + \alpha_1 z_t + \alpha_2 z_{t-1} + \beta_0 s_{t+1} + \beta_1 s_t] = 0,$$

where

$$\mathcal{E}_t X_t = \begin{bmatrix} E[X_{1t} | \hat{\epsilon}_{t-1}] \\ E[X_{2t} | \hat{\epsilon}_t] \end{bmatrix}.$$

- Convenient to Change  $s_t$ :

$$s_t = \begin{pmatrix} \hat{\epsilon}_t \\ \hat{\epsilon}_{t-1} \end{pmatrix}, \quad P = \begin{bmatrix} \rho & 0 \\ 1 & 0 \end{bmatrix}, \quad \epsilon_t = \begin{pmatrix} e_t \\ 0 \end{pmatrix}.$$

- Adjust  $\beta_i$ 's:

$$\beta_0 = \begin{pmatrix} v_{K,6\epsilon} & 0 \\ 0 & 0 \end{pmatrix}, \quad \beta_1 = \begin{pmatrix} v_{K,7\epsilon} & 0 \\ v_{N,4\epsilon} & 0 \end{pmatrix},$$

#### Example #4: Example #3 With ‘Exotic’ Information Set ...

- Posit Following Solution:

$$z_t = Az_{t-1} + Bs_t.$$

- Substitute Into Canonical Form:

$$\begin{aligned} & \mathcal{E}_t [\alpha_0 z_{t+1} + \alpha_1 z_t + \alpha_2 z_{t-1} + \beta_0 s_{t+1} + \beta_1 s_t] \\ &= \alpha(A)z_{t-1} + \mathcal{E}_t F s_t + \mathcal{E}_t \beta_0 \epsilon_{t+1} = \alpha(A)z_{t-1} + \mathcal{E}_t F s_t = 0, \end{aligned}$$

- Then,

$$\begin{aligned} \mathcal{E}_t F s_t &= \mathcal{E}_t \begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix} s_t = \mathcal{E}_t \begin{bmatrix} F_{11}\hat{\epsilon}_t + F_{12}\hat{\epsilon}_{t-1} \\ F_{21}\hat{\epsilon}_t + F_{22}\hat{\epsilon}_{t-1} \end{bmatrix} \\ &= \begin{bmatrix} 0 & F_{12} + \rho F_{11} \\ F_{21} & F_{22} \end{bmatrix} s_t = \tilde{F} s_t. \end{aligned}$$

- Equations to be solved:

$$\alpha(A) = 0, \quad \tilde{F} = 0.$$

- $\tilde{F}$  Only Has *Three* Equations How Can We Solve for the Four Elements of  $B$ ?
- Answer: Only *Three* Unknowns in  $B$  Because  $B$  Must Also Obey Information Structure:

$$B = \begin{bmatrix} 0 & B_{12} \\ B_{21} & B_{22} \end{bmatrix}.$$

# Summary so Far

---

- Solving Models By Log Linear Approximation Involves Three Steps:
  - a. Compute Steady State
  - b. Log-Linearize Equilibrium Conditions
  - c. Solve Log Linearized Equations.

- Step 3 Requires Finding  $A$  and  $B$  in:

$$z_t = Az_{t-1} + Bs_t,$$

to Satisfy Log-Linearized Equilibrium Conditions:

$$\mathcal{E}_t [\alpha_0 z_{t+1} + \alpha_1 z_t + \alpha_2 z_{t-1} + \beta_0 s_{t+1} + \beta_1 s_t]$$

$$s_t = Ps_{t-1} + \epsilon_t, \epsilon_t \sim \text{iid}$$

- We are Led to Choose  $A$  and  $B$  so that:

$$\alpha(A) = 0,$$

$$(\text{standard information set}) F = 0,$$

$$(\text{exotic information set}) \tilde{F} = 0$$

and Eigenvalues of  $A$  are Less Than Unity In Absolute Value.

# Example #5: A Sticky Price Model (Clarida-Gali-Gertler)

---

- Technology grows forever: equilibrium of model has no constant steady state.
- Deviations of the equilibrium from a particular benchmark does have a steady state.
  - Benchmark: best equilibrium given preferences and production technology
    - \* ‘natural equilibrium’ (later, will investigate whether benchmark is achievable by some monetary/fiscal policy)
  - Natural equilibrium is trivial to compute because of absence of capital.
- Model is approximately log-linear around natural equilibrium allocations.

## Example #5: A Sticky Price Model (Clarida-Gali-Gertler) ...

- Model:
  - Households choose consumption and labor.
  - Monopolistic firms produce and sell output using labor, subject to sticky prices
  - Monetary authority obeys a Taylor rule.

# Household

---

- Preferences & budget constraint:

$$E_0 \sum_{t=0}^{\infty} \beta^t \left( \log C_t - \exp(\tau_t) \frac{N_t^{1+\varphi}}{1+\varphi} - v \frac{\left(\frac{P_t C_t}{M_t^d}\right)^{1+\sigma_q}}{1+\sigma_q} \right), \quad \tau_t = \lambda \tau_{t-1} + \varepsilon_t^\tau.$$

$$P_t C_t + M_t^d + B_{t+1} \leq M_{t-1}^d + B_t R_{t-1} + W_t N_t + \text{Transfers and profits}_t$$

- Household efficiency conditions (ignore money because  $v$  is small):

$$C_t^{-1} = \beta E_t C_{t+1}^{-1} R_t / \bar{\pi}_{t+1},$$

$$\bar{\pi}_{t+1} \equiv \frac{P_{t+1}}{P_t},$$

$$MRS_t = \exp(\tau_t) N_t^\varphi C_t = \frac{W_t}{P_t}.$$

# Firms

---

- Final Good Firms (simple!)

- Buy  $Y_{i,t}$ ,  $i \in [0, 1]$  at prices  $P_{i,t}$  and sell  $Y_t$  at price  $P_t$

- Technology:

$$Y_t = \left( \int_0^1 Y_{i,t}^{\frac{\varepsilon-1}{\varepsilon}} di \right)^{\frac{\varepsilon}{\varepsilon-1}}, \quad \varepsilon \geq 1. \quad (1)$$

- Demand for intermediate good (fonc for optimization of  $Y_{i,t}$ ):

$$Y_{i,t} = Y_t \left( \frac{P_{i,t}}{P_t} \right)^{-\varepsilon} \quad (2)$$

- Eqs (6) and (2) imply:

$$P_t = \left( \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right)^{\frac{1}{1-\varepsilon}} \quad (3)$$

## Firms ...

- Intermediate Good Firms (an astounding amount of algebra!)

– Technology:

$$Y_{i,t} = A_t N_{i,t}, \quad a_t = \log A_t,$$

$$\Delta a_t = \rho \Delta a_{t-1} + \varepsilon_t.$$

– Marginal cost of production for  $i^{th}$  firm (with subsidy,  $\nu_t$ ) :

$$s_t = \underbrace{(1 - \nu_t)}_{\text{net of subsidy}} \underbrace{\frac{W_t}{A_t P_t}}_{\text{'Normal' Marginal Cost}} \underbrace{(1 - \psi + \psi R_t)}_{\text{fraction, } \psi, \text{ of labor costs requires bank finance}}$$

– Calvo price-setting frictions:

- \* A fraction,  $\theta$ , of intermediate good firms cannot change price:

$$P_{i,t} = P_{i,t-1}$$

- \* A fraction,  $1 - \theta$ , set price optimally:

$$P_{i,t} = \tilde{P}_t$$

## Firms ...

- Decision of intermediate good firm
  - Only choice problem: optimize price,  $P_{i,t}$ , whenever opportunity arises.
  - Otherwise, always produce the quantity dictated by demand.
- The firm's periodic optimization gives rise to equilibrium conditions needed to solve the model.
  - Ultimate equilibrium conditions simple.
  - Lot's of (simple) algebra to get them.

## Firms ...

- Solving intermediate good firm optimization problem
  - Discounted profits:

$$E_t \sum_{j=0}^{\infty} \beta^j \underbrace{\text{Lagrange multiplier on household budget constraint}}_{v_{t+j}} \overbrace{\left[ \underbrace{P_{i,t+j} Y_{i,t+j}}_{\text{revenues}} - \underbrace{P_{t+j} s_{t+j} Y_{i,t+j}}_{\text{total cost}} \right]}^{\text{period } t+j \text{ profits sent to household}}$$

- Each of the  $1 - \theta$  firms that have opportunity to reoptimize price,  $P_{i,t}$ , select  $\tilde{P}_t$  so maximize:

in selecting price, firm only cares about future states in which it can't reoptimize

$$E_t \sum_{j=0}^{\infty} \beta^j \underbrace{\theta^j}_{\text{in which it can't reoptimize}} v_{t+j} \left[ \tilde{P}_t Y_{i,t+j} - P_{t+j} s_{t+j} Y_{i,t+j} \right].$$

## Firms ...

- Substitute out for intermediate good firm output using demand curve:

$$\begin{aligned}
 & E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} [\tilde{P}_t Y_{i,t+j} - P_{t+j} s_{t+j} Y_{i,t+j}] \\
 &= E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} Y_{t+j} P_{t+j}^{\varepsilon} [\tilde{P}_t^{1-\varepsilon} - P_{t+j} s_{t+j} \tilde{P}_t^{-\varepsilon}].
 \end{aligned}$$

- Differentiate with respect to  $\tilde{P}_t$  :

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} Y_{t+j} P_{t+j}^{\varepsilon} \left[ (1 - \varepsilon) (\tilde{P}_t)^{-\varepsilon} + \varepsilon P_{t+j} s_{t+j} \tilde{P}_t^{-\varepsilon-1} \right] = 0,$$

or,

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j v_{t+j} Y_{t+j} P_{t+j}^{\varepsilon+1} \left[ \frac{\tilde{P}_t}{P_{t+j}} - \frac{\varepsilon}{\varepsilon - 1} s_{t+j} \right] = 0.$$

- When  $\theta = 0$ , get standard result - price is fixed markup over marginal cost.

## Firms ...

- Substitute out the multiplier:

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j \overbrace{\frac{u'(C_{t+j})}{P_{t+j}}}^{\text{marginal utility of a dollar} = v_{t+j}} Y_{t+j} P_{t+j}^{\varepsilon+1} \left[ \frac{\tilde{P}_t}{P_{t+j}} - \frac{\varepsilon}{\varepsilon-1} s_{t+j} \right] = 0.$$

- Use utility functional form and goods market clearing condition,  $C_{t+j} = Y_{t+j}$  :

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j P_{t+j}^{\varepsilon} \left[ \frac{\tilde{P}_t}{P_{t+j}} - \frac{\varepsilon}{\varepsilon-1} s_{t+j} \right] = 0.$$

or,

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{-\varepsilon} \left[ \tilde{p}_t X_{t,j} - \frac{\varepsilon}{\varepsilon-1} s_{t+j} \right] = 0,$$

$$\tilde{p}_t = \frac{\tilde{P}_t}{P_t}, \quad X_{t,j} = \begin{cases} \frac{1}{\bar{\pi}_{t+j}\bar{\pi}_{t+j-1}\dots\bar{\pi}_{t+1}}, & j \geq 1 \\ 1, & j = 0. \end{cases}, \quad X_{t,j} = X_{t+1,j-1} \frac{1}{\bar{\pi}_{t+1}}, \quad j > 0$$

## Firms ...

- Want  $\tilde{p}_t$  in:

$$E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{-\varepsilon} \left[ \tilde{p}_t X_{t,j} - \frac{\varepsilon}{\varepsilon - 1} s_{t+j} \right] = 0$$

- Solve for  $\tilde{p}_t$  :

$$\tilde{p}_t = \frac{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j}}{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{1-\varepsilon}} = \frac{K_t}{F_t},$$

- We've almost finished solving the intermediate firm problem!
- But, still need expressions for  $K_t$ ,  $F_t$ .

## Firms ...

$$\begin{aligned}
K_t &= E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} s_{t+j} \\
&= \frac{\varepsilon}{\varepsilon - 1} s_t + \beta\theta E_t \sum_{j=1}^{\infty} (\beta\theta)^{j-1} \left( \frac{1}{\bar{\pi}_{t+1}} X_{t+1,j-1} \right)^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} s_{t+j} \\
&= \frac{\varepsilon}{\varepsilon - 1} s_t + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} \sum_{j=0}^{\infty} (\beta\theta)^j X_{t+1,j}^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} s_{t+1+j} \\
&= \frac{\varepsilon}{\varepsilon - 1} s_t + \beta\theta \overbrace{E_t E_{t+1}}^{=E_t \text{ by LIME}} \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} \sum_{j=0}^{\infty} (\beta\theta)^j X_{t+1,j}^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} s_{t+1+j} \\
&= \frac{\varepsilon}{\varepsilon - 1} s_t + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} \overbrace{\sum_{j=0}^{\infty} (\beta\theta)^j X_{t+1,j}^{-\varepsilon} \frac{\varepsilon}{\varepsilon - 1} s_{t+1+j}}^{\text{exactly } K_{t+1}!} \\
&= \frac{\varepsilon}{\varepsilon - 1} s_t + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} K_{t+1}
\end{aligned}$$

**Firms ...**

- So,

$$K_t = \frac{\varepsilon}{\varepsilon - 1} s_t + \beta \theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} K_{t+1}.$$

- Simplify marginal cost term:

$$\begin{aligned} \frac{\varepsilon}{\varepsilon - 1} s_t &= \frac{\varepsilon}{\varepsilon - 1} (1 - \nu_t) \frac{W_t}{A_t P_t} (1 - \psi + \psi R_t) \\ &= \frac{\varepsilon}{\varepsilon - 1} (1 - \nu_t) \overbrace{\frac{W_t}{P_t} \text{ by household optimization}}^{\exp(\tau_t) N_t^\varphi C_t} \frac{1 - \psi + \psi R_t}{A_t}. \end{aligned}$$

**Firms ...**

• Conclude:

– Optimal price:

$$\tilde{p}_t = \frac{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{-\varepsilon} \frac{\varepsilon}{\varepsilon-1} s_{t+j}}{E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{1-\varepsilon}} = \frac{K_t}{F_t},$$

where

$$K_t = (1 - \nu_t) \frac{\varepsilon}{\varepsilon - 1} \frac{\exp(\tau_t) N_t^\varphi C_t}{A_t} (1 - \psi + \psi R_t) + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{-\varepsilon} K_{t+1}.$$

Similarly,

$$F_t \equiv E_t \sum_{j=0}^{\infty} (\beta\theta)^j (X_{t,j})^{1-\varepsilon} = 1 + \beta\theta E_t \left( \frac{1}{\bar{\pi}_{t+1}} \right)^{1-\varepsilon} F_{t+1}$$

## Firms ...

- We now have optimization conditions for households and firms.
  
- Need some aggregate conditions:
  - Relationship among prices
  
  - Relationship between aggregate inputs (e.g., technology,  $A_t$ , and labor,  $N_t$ ) and aggregate output (e.g.,  $Y_t$ ).

## Firms ...

- Aggregate Price Relationship

$$P_t = \left[ \int_0^1 P_{i,t}^{(1-\varepsilon)} di \right]^{\frac{1}{1-\varepsilon}}$$

$$= \left[ \int_{\text{firms that reoptimize price}} P_{i,t}^{(1-\varepsilon)} di + \int_{\text{firms that don't reoptimize price}} P_{i,t}^{(1-\varepsilon)} di \right]^{\frac{1}{1-\varepsilon}}$$

all reoptimizers choose same price  $\underbrace{\hspace{1.5cm}}_{\equiv}$

$$\left[ (1 - \theta) \tilde{P}_t^{(1-\varepsilon)} + \int_{\text{firms that don't reoptimize price}} P_{i,t}^{(1-\varepsilon)} di \right]^{\frac{1}{1-\varepsilon}}$$

## Firms ...

- Rewrite integral of prices of intermediate good firms that do not reoptimize:

$$\int_{\text{firms that don't reoptimize price in } t} P_{i,t}^{(1-\varepsilon)} di$$

add over prices, weighted by # of firms posting that price

$$\int \left[ \overbrace{\text{'number' of firms that had price, } P(\omega), \text{ in } t-1 \text{ and were not able to reoptimize in } t}^{f_{t-1,t}(\omega)} P(\omega)^{(1-\varepsilon)} \right] d\omega$$

In principle, HARD integral to evaluate!

## Firms ...

- By Calvo randomization assumption:

$$f_{t-1,t}(\omega) = \theta \times \overbrace{f_{t-1}(\omega)}^{\text{total 'number' of firms with price } P(\omega) \text{ in } t-1}, \text{ for all } \omega$$

- Substituting:

$$\begin{aligned} \int_{\text{firms that don't reoptimize price}} P_{i,t}^{(1-\varepsilon)} di &= \int f_{t-1,t}(\omega) P(\omega)^{(1-\varepsilon)} d\omega \\ &= \theta \int f_{t-1}(\omega) P(\omega)^{(1-\varepsilon)} d\omega \\ &= \theta P_{t-1}^{(1-\varepsilon)} \end{aligned}$$

- Trivial!

## Firms ...

- Conclude that the following relationship holds between prices:

$$P_t = \left[ (1 - \theta) \tilde{P}_t^{(1-\varepsilon)} + \theta P_{t-1}^{(1-\varepsilon)} \right]^{\frac{1}{1-\varepsilon}}.$$

- Divide by  $P_t$  :

$$1 = \left[ (1 - \theta) \tilde{p}_t^{(1-\varepsilon)} + \theta \left( \frac{1}{\bar{\pi}_t} \right)^{(1-\varepsilon)} \right]^{\frac{1}{1-\varepsilon}}$$

- Rearrange:

$$\tilde{p}_t = \left[ \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right]^{\frac{1}{1-\varepsilon}}$$

## Firms ...

- Aggregate inputs and outputs

- Technically, there is no ‘aggregate production function’:

i.e., simple relationship between output,  $Y_t$ , and aggregate inputs,  $N_t$ ,  $A_t$

- Aggregate output,  $Y_t$ , is not only a function of total labor input,  $N_t$ , and  $A_t$ , but also of the *distribution* of labor input among intermediate goods.

- Tak Yun (JME) developed a simple characterization of the connection between  $N$ ,  $A$ ,  $Y$  and the distribution of resources.

## Firms ...

– Define  $Y_t^*$ :

$$Y_t^* = \int_0^1 Y_{i,t} di \left( = \int_0^1 A_t N_{i,t} di \quad \underbrace{\quad}_{\text{labor market clearing}} \quad A_t N_t \right)$$

$$\underbrace{\quad}_{\text{demand curve}} Y_t \int_0^1 \left( \frac{P_{i,t}}{P_t} \right)^{-\varepsilon} di$$

$$= Y_t P_t^\varepsilon \int_0^1 (P_{i,t})^{-\varepsilon} di$$

$$= Y_t P_t^\varepsilon (P_t^*)^{-\varepsilon}$$

where

$$P_t^* \equiv \left[ \int_0^1 P_{i,t}^{-\varepsilon} di \right]^{\frac{-1}{\varepsilon}} = \left[ (1 - \theta) \tilde{P}_t^{-\varepsilon} + \theta (P_{t-1}^*)^{-\varepsilon} \right]^{\frac{-1}{\varepsilon}}$$

## Firms ...

- Relationship between aggregate inputs and outputs:

$$\begin{aligned} Y_t &= \left( \frac{P_t^*}{P_t} \right)^\varepsilon Y_t^* \\ &= p_t^* A_t N_t, \end{aligned}$$

where

$$p_t^* \equiv \left( \frac{P_t^*}{P_t} \right)^\varepsilon .$$

- ‘Efficiency distortion’,  $p_t^*$ :

$$p_t^* : \begin{cases} \leq 1 \\ = 1 & P_{i,t} = P_{j,t}, \text{ all } i, j \end{cases}$$

- When prices of different intermediate goods differ, then resources allocated inefficiently.

## Firms ...

– Example:

$$P_{j,t} = \begin{cases} P^1 & 0 \leq j \leq \alpha \\ P^2 & \alpha \leq j \leq 1 \end{cases} .$$

– Then

$$p_t^* = \left( \frac{P_t^*}{P_t} \right)^\varepsilon = \left( \frac{\left[ \alpha + (1 - \alpha) \left( \frac{P^2}{P^1} \right)^{-\varepsilon} \right]^{\frac{-1}{\varepsilon}}}{\left[ \alpha + (1 - \alpha) \left( \frac{P^2}{P^1} \right)^{1-\varepsilon} \right]^{\frac{1}{1-\varepsilon}}} \right)^\varepsilon$$

$\alpha = 0.5$   $\varepsilon = 5$   
distortion,  $p^*$

## Firms ...

- Bottom line:

- Combining efficiency condition of intermediate firms with household static efficiency:

$$K_t = (1 - \nu_t) \frac{\varepsilon}{\varepsilon - 1} \frac{\exp(\tau_t) N_t^\varphi C_t}{A_t} (1 - \psi + \psi R_t) + \beta \theta E_t \bar{\pi}_{t+1}^\varepsilon K_{t+1} \quad (1)$$

$$F_t = 1 + \beta \theta E_t \bar{\pi}_{t+1}^{\varepsilon-1} F_{t+1} \quad (2)$$

- Intermediate good firm optimality and restriction across prices:

$$\begin{aligned} & \overset{=\tilde{p}_t \text{ by firm optimality}}{\underbrace{\frac{K_t}{F_t}}} = \overset{=\tilde{p}_t \text{ by restriction across prices}}{\left[ \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right]^{\frac{1}{1-\varepsilon}}} \quad (3) \end{aligned}$$

## Firms ...

- Law of motion for efficiency distortion:

$$p_t^* = \left[ (1 - \theta) \left( \frac{1 - \theta \bar{\pi}_t^{(\varepsilon-1)}}{1 - \theta} \right)^{\frac{\varepsilon}{\varepsilon-1}} + \frac{\theta \bar{\pi}_t^\varepsilon}{p_{t-1}^*} \right]^{-1} \quad (4)$$

- Household intertemporal condition:

$$\frac{1}{C_t} = \beta E_t \frac{1}{C_{t+1}} \frac{R_t}{\bar{\pi}_{t+1}} \quad (5)$$

- Aggregate inputs and outputs:

$$C_t = p_t^* A_t N_t \quad (6)$$

- 8 unknowns -  $\nu_t, C_t, p_t^*, N_t, \bar{\pi}_t, K_t, F_t, R_t$  - 6 equations.

- Need to find more equations to close the model!

## Firms ...

- Closing the model: optimal and exogenous policy.

– Choose optimal policy (I substituted out  $C_t$ ):

$$\begin{aligned}
 & \max_{\nu_t, p_t^*, N_t, R_t, \bar{\pi}_t, F_t, K_t} E_0 \sum_{t=0}^{\infty} \beta^t \left\{ \left( \log N_t + \log p_t^* - \exp(\tau_t) \frac{N_t^{1+\varphi}}{1+\varphi} \right) \right. \\
 & + \lambda_{1t} \left[ \frac{1}{p_t^* N_t} - E_t \frac{A_t \beta}{p_{t+1}^* A_{t+1} N_{t+1} \bar{\pi}_{t+1}} R_t \right] \\
 & + \lambda_{2t} \left[ \frac{1}{p_t^*} - \left( (1-\theta) \left( \frac{1-\theta (\bar{\pi}_t)^{\varepsilon-1}}{1-\theta} \right)^{\frac{\varepsilon}{\varepsilon-1}} + \frac{\theta \bar{\pi}_t^\varepsilon}{p_{t-1}^*} \right) \right] \\
 & + \lambda_{3t} \left[ 1 + E_t \bar{\pi}_{t+1}^{\varepsilon-1} \beta \theta F_{t+1} - F_t \right] \\
 & + \lambda_{4t} \left[ (1-\nu_t) \frac{\varepsilon}{\varepsilon-1} \exp(\tau_t) N_t^{1+\varphi} p_t^* (1-\psi + \psi R_t) + E_t \beta \theta \bar{\pi}_{t+1}^\varepsilon K_{t+1} - K_t \right] \\
 & \left. + \lambda_{5t} \left[ F_t \left[ \frac{1-\theta \bar{\pi}_t^{\varepsilon-1}}{1-\theta} \right]^{\frac{1}{1-\varepsilon}} - K_t \right] \right\}
 \end{aligned}$$

## Firms ...

### – Optimal policy

- \* Unknowns: 7 plus 5 multipliers = 12.
- \* Equations: 5 plus 7 first order conditions = 12
- \* Can solve this system using the linearization methods
- \* Can ask: should we stabilize inflation,  $\bar{\pi}_t$ , the price level,  $P_t$ ?
- \* More on this later...

## Firms ...

- Another way to close the model: add two exogenous equations (Taylor rule and specification of  $\nu_t$ )
  - A standard formulation of Taylor rule policy focuses on ‘natural’ equilibrium (equilibrium in which relative price distortions have been eliminated and employment is not distorted by monopoly power) as benchmark.
  - Consider a policy that eliminates the ‘labor wedge’ in steady state and sets  $\bar{\pi} = 1$ .
- Steady state (delete time subscripts from the 5 equilibrium conditions and solve):

$$R = \frac{1}{\beta}, p^* = 1, F = K = \frac{1}{1 - \beta\theta}, N = \exp\left(-\frac{\tau}{1 + \varphi}\right) = 1 \text{ (since } \tau = 0\text{)}.$$

## Firms ...

- Natural equilibrium: absence of price distortions induces cross-industry efficiency:

$$N_{i,t} = N_t \text{ all } i$$

so that

$$Y_t = A_t N_t, \quad y_t = a_t + n_t \quad (4)$$

- Labor market efficiency (in logs):

$$\underbrace{\log MRS_t}_{c_t + \varphi n_t + \tau_t} = \underbrace{\log MP_{L,t}}_{a_t} \quad (5)$$

- Combine (4) and (5):

$$a_t = y_t + \varphi (y_t - a_t) + \tau_t$$

so that natural level of output and employment is:

$$y_t^* = a_t - \frac{1}{1 + \varphi} \tau_t, \quad n_t^* = y_t^* - a_t = -\frac{1}{1 + \varphi} \tau_t$$

## Firms ...

- Interest rate in the ‘natural’ equilibrium steers households to choose efficient levels of employment and consumption.
  - Household intertemporal Euler equation:

$$C_t^{-1} = \beta E_t C_{t+1}^{-1} R_t / \bar{\pi}_{t+1}.$$

- In logs:

$$\begin{aligned} -c_t &= \log \beta + r_t + \log [E_t C_{t+1}^{-1} / \bar{\pi}_{t+1}] \\ &= \log \beta + r_t + \log [E_t \exp(-c_{t+1} - \pi_{t+1})] \\ &\simeq \log \beta + r_t + \log [\exp(-E_t c_{t+1} - E_t \pi_{t+1})] \\ &= r_t - rr - E_t c_{t+1} - E_t \pi_{t+1} \end{aligned}$$

$$rr \equiv -\log \beta$$

## Firms ...

- Intertemporal Euler equation (repeated)

$$c_t = - [r_t - E_t \pi_{t+1} - rr] + E_t c_{t+1}$$

- To determine ‘natural’ real interest rate,  $rr_t^*$ , substitute ‘natural’ output,  $y_t^*$ , and inflation,  $\pi_t = 0$ , into household Euler equation:

$$\overbrace{a_t - \frac{1}{1+\varphi} \tau_t}^{y_t^*} = - [rr_t^* - rr] + E_t \left( \overbrace{a_{t+1} - \frac{1}{1+\varphi} \tau_{t+1}}^{y_{t+1}^*} \right)$$

or,

$$rr_t^* = rr + \rho \Delta a_t + \frac{1}{1+\varphi} (1-\lambda) \tau_t.$$

- Recall:

$$\tau_t = \lambda \tau_{t-1} + \varepsilon_t^\tau, \quad \Delta a_t = \rho \Delta a_{t-1} + \varepsilon_t$$

## Firms ...

- Natural rate:

$$rr_t^* = rr + \rho \Delta a_t + \frac{1}{1 + \varphi} (1 - \lambda) \tau_t.$$

- $\Delta a_t$  jumps

- \*  $a_t$  will keep rising in future (if  $\rho > 0$ )
- \* rise in  $c_t^*$  smaller than rise in  $c_{t+1}^*$
- \* people would like to use financial markets to smooth away from this
- \* discourage this by having a high interest rate.

- $\tau_t$  jumps

- \*  $\tau_t$  will be less high in the future (unless  $\lambda > 1$ )
- \*  $c_t^*$  falls more than  $c_t^*$
- \* people want to smooth away
- \* discourage this by having a high interest rate.

## Firms ...

- Taylor Rule

- Target interest rate,  $\hat{r}_t$  :

$$\hat{r}_t = rr + \phi_\pi \pi_t + \phi_x x_t, \quad x_t \equiv y_t - y_t^*.$$

- Actual interest rate,  $r_t$  :

$$r_t = \alpha r_{t-1} + (1 - \alpha) \hat{r}_t + u_t$$

$$u_t = \delta u_{t-1} + \eta_t.$$

- Policy rule:

$$r_t - rr = \alpha (r_{t-1} - rr) + u_t + (1 - \alpha) \phi_\pi \pi_t + (1 - \alpha) \phi_x x_t$$

## Firms ...

- Intertemporal equations:

$$\text{Taylor rule equilibrium: } y_t = - [r_t - E_t \pi_{t+1} - rr] + E_t y_{t+1}$$

$$\text{Natural equilibrium: } y_t^* = - [rr_t^* - rr] + E_t y_{t+1}^*$$

- Subtract, to obtain ‘New Keynesian IS equation’:

$$x_t = - [r_t - E_t \pi_{t+1} - rr_t^*] + E_t x_{t+1}$$

## Firms ...

- With Taylor rule, cannot rule out fluctuations in inflation. So, in presence of shocks  $N_{i,t}$  varies across  $i$  and:

$$y_t = \log p_t^* + n_t + a_t, \quad \log p_t^* = \begin{cases} = 0 & \text{if } P_{i,t} = P_{j,t} \text{ for all } i, j \\ \leq 0 & \text{otherwise} \end{cases} .$$

- Along a nonstochastic steady state, zero inflation growth path,  $\log p_t^* = 0$ . Log-linear expansion of equilibrium law of motion for  $p_t^*$  yields:

$$\hat{p}_t^* \approx \theta \hat{p}_{t-1}^* + 0 \times \bar{\pi}_t$$

- We still need the equilibrium conditions associated with sticky prices.

## Firms ...

- Log-linearizing each sticky price equilibrium condition (i.e., equilibrium conditions, 3-5) respectively:

$$\beta\theta E_t \left[ (\varepsilon - 1) \widehat{\pi}_{t+1} + \widehat{F}_{t+1} \right] = \widehat{F}_t \quad (3)$$

$$d\tau_t + (1 + \varphi) \widehat{N}_t + \frac{R\psi}{1 - \psi + \psi R} \widehat{R}_t + \frac{\beta\theta}{1 - \beta\theta} E_t \left[ \varepsilon \widehat{\pi}_{t+1} + \widehat{K}_{t+1} \right] = \frac{1}{1 - \beta\theta} \widehat{K}_t \quad (4)$$

$$\widehat{F}_t + \frac{\theta}{1 - \theta} \widehat{\pi}_t = \widehat{K}_t \quad (5)$$

- equations (3)-(5) reduce to the usual Phillips curve

– substitute (5) into (4)

$$\begin{aligned} & d\tau_t + (1 + \varphi) \widehat{N}_t + \widehat{p}_t^* + \frac{R\psi}{1 - \psi + \psi R} \widehat{R}_t + \frac{\beta\theta}{1 - \beta\theta} E_t \left[ \varepsilon \widehat{\pi}_{t+1} + \widehat{F}_{t+1} + \frac{\theta}{1 - \theta} \widehat{\pi}_{t+1} \right] \\ &= \frac{1}{1 - \beta\theta} \left[ \widehat{F}_t + \frac{\theta}{1 - \theta} \widehat{\pi}_t \right] \end{aligned}$$

## Firms ...

- substitute (3) into the previous expression, and rearrange:

$$\widehat{\pi}_t = \frac{(1 - \beta\theta)(1 - \theta)}{\theta} \overbrace{\left[ d\tau_t + (1 + \varphi) \hat{N}_t + \frac{R\psi}{1 - \psi + \psi R} \hat{R}_t \right]}^{\text{percent deviation of real marginal cost from ss}} + \beta \widehat{\pi}_{t+1},$$

- Note:

$$x_t = y_t - y_t^* = a_t + n_t - \left[ a_t - \frac{1}{1 + \varphi} \tau_t \right] = n_t + \frac{1}{1 + \varphi} \tau_t,$$

so (recall,  $\hat{N}_t = \log(N_t/N) = \log(N_t)$ ,  $d\tau_t = \tau_t - \tau = \tau_t$ )

$$\widehat{\pi}_t = \frac{(1 - \beta\theta)(1 - \theta)}{\theta} (1 + \varphi) \left[ x_t + \frac{R\psi}{(1 + \varphi)(1 - \psi + \psi R)} \hat{R}_t \right] + \beta \widehat{\pi}_{t+1},$$

- We now have three equations ('IS curve, Phillips curve and policy rule') in three unknowns:  $\pi_t$ ,  $r_t$ ,  $x_t$ .

# Equations of Taylor rule Equilibrium ( $\psi = 0$ )

---

$$\beta E_t \pi_{t+1} + \kappa x_t - \pi_t = 0 \text{ (Calvo pricing equation)}$$

$$- [r_t - E_t \pi_{t+1} - r r_t^*] + E_t x_{t+1} - x_t = 0 \text{ (intertemporal equation)}$$

$$\alpha r_{t-1} + u_t + (1 - \alpha) \phi_\pi \pi_t + (1 - \alpha) \phi_x x_t - r_t = 0 \text{ (policy rule)}$$

$$r r_t^* - \rho \Delta a_t - \frac{1}{1 + \varphi} (1 - \lambda) \tau_t = 0 \text{ (definition of natural rate)}$$

- $r_t$  and  $r r_t^*$  expressed in deviations from steady state
- Preference and technology shocks enter system through  $r r_t^*$
- Optimal equilibrium can be supported by setting nominal rate to natural rate:

$$r_t = r r_t^*.$$

- Practical issue: how to measure  $r r_t^*???$

# Solving the Sticky Price Model

---

- Exogenous shocks:

$$s_t = \begin{pmatrix} \Delta a_t \\ u_t \\ \tau_t \end{pmatrix} = \begin{bmatrix} \rho & 0 & 0 \\ 0 & \delta & 0 \\ 0 & 0 & \lambda \end{bmatrix} \begin{pmatrix} \Delta a_{t-1} \\ u_{t-1} \\ \tau_{t-1} \end{pmatrix} + \begin{pmatrix} \varepsilon_t \\ \eta_t \\ \varepsilon_t^\tau \end{pmatrix}$$

$$s_t = P s_{t-1} + \epsilon_t$$

- Equilibrium conditions:

$$\begin{bmatrix} \beta & 0 & 0 & 0 \\ \frac{1}{\sigma} & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{pmatrix} \pi_{t+1} \\ x_{t+1} \\ r_{t+1} \\ rr_{t+1}^* \end{pmatrix} + \begin{bmatrix} -1 & \kappa & 0 & 0 \\ 0 & -1 & -\frac{1}{\sigma} & \frac{1}{\sigma} \\ (1-\alpha)\phi_\pi & (1-\alpha)\phi_x & -1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{pmatrix} \pi_t \\ x_t \\ r_t \\ rr_t^* \end{pmatrix}$$

$$+ \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & \alpha & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{pmatrix} \pi_{t-1} \\ x_{t-1} \\ r_{t-1} \\ rr_{t-1}^* \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} s_{t+1} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \\ -\sigma\psi\rho & 0 & -\frac{1}{\sigma+\varphi}(1-\lambda) \end{pmatrix} s_t$$

$$E_t [\alpha_0 z_{t+1} + \alpha_1 z_t + \alpha_2 z_{t-1} + \beta_0 s_{t+1} + \beta_1 s_t] = 0$$

## Solving the Sticky Price Model ...

- Collecting:

$$E_t [\alpha_0 z_{t+1} + \alpha_1 z_t + \alpha_2 z_{t-1} + \beta_0 s_{t+1} + \beta_1 s_t] = 0$$

$$s_t - P s_{t-1} - \epsilon_t = 0.$$

- Solution:

$$z_t = A z_{t-1} + B s_t$$

- As before, want  $A$  such that

$$\alpha_0 A^2 + \alpha_1 A + \alpha_2 = 0,$$

- Want  $B$  such that:

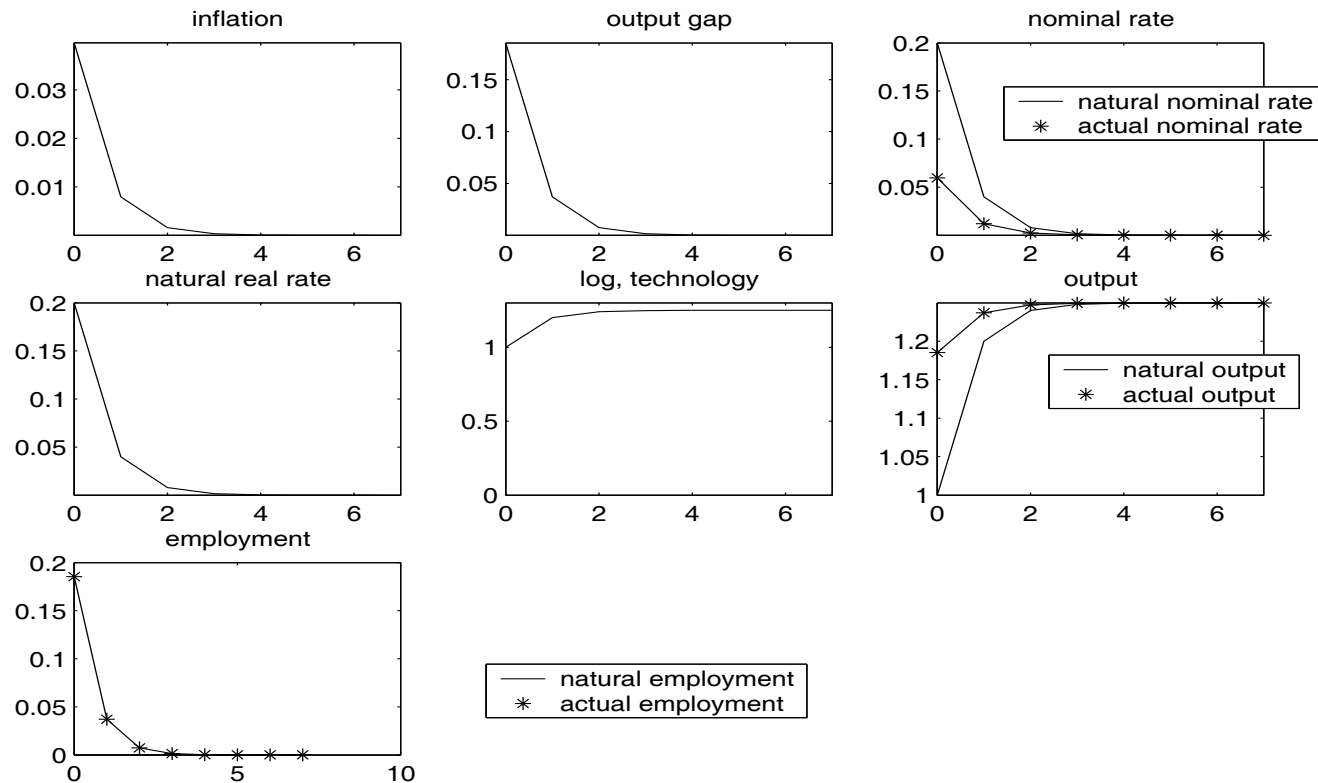

$$F = (\beta_0 + \alpha_0 B)P + [\beta_1 + (\alpha_0 A + \alpha_1)B] = 0$$

- Note: if  $\alpha = 0$ ,  $A = 0$ .

# Examples with Sticky Price Model

$$\phi_x = 0, \phi_\pi = 1.5, \beta = 0.99, \varphi = 1, \rho = 0.2, \theta = 0.75, \alpha = 0, \delta = 0.2, \lambda = 0.5.$$

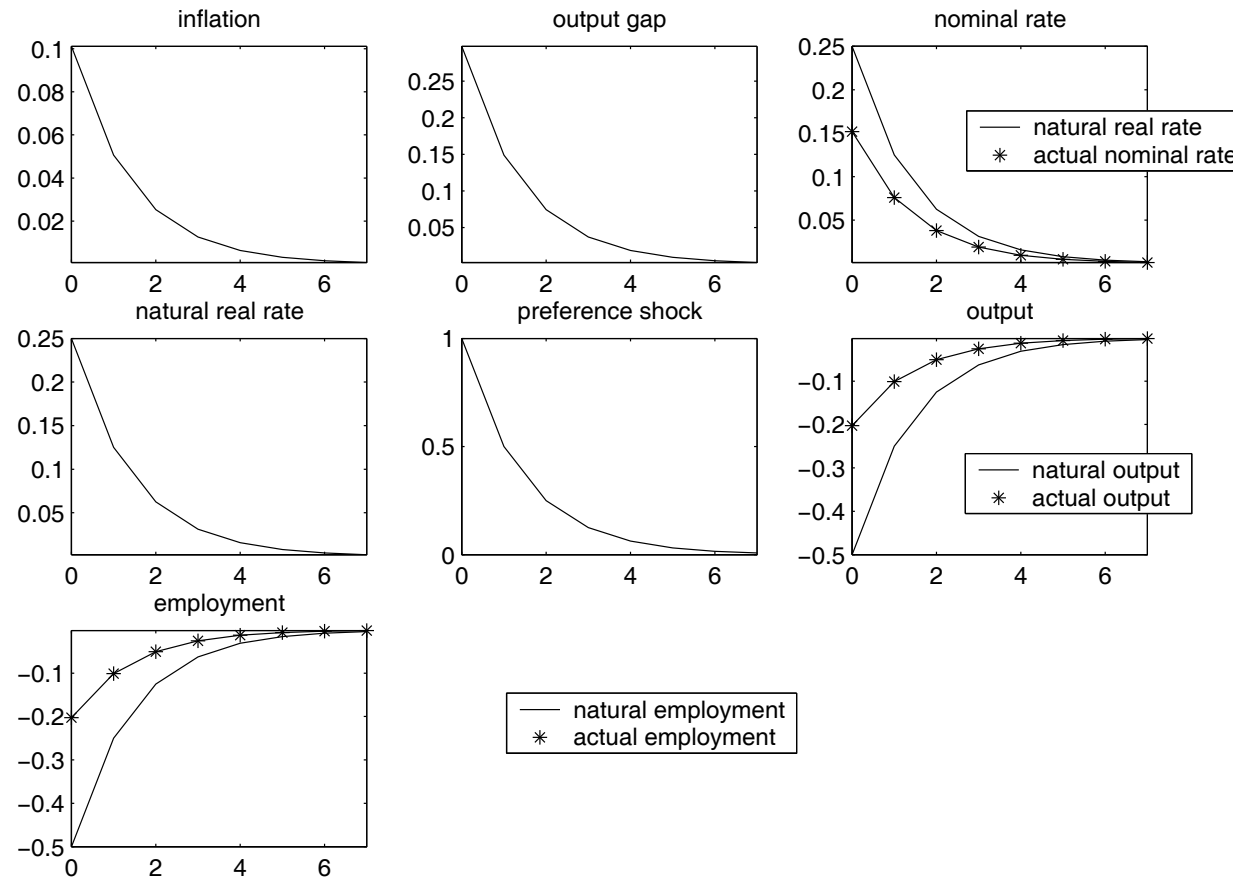

Dynamic Response to a Technology Shock

- Interest rate not increased enough, employment and inflation rise.

## Examples with Sticky Price Model ...

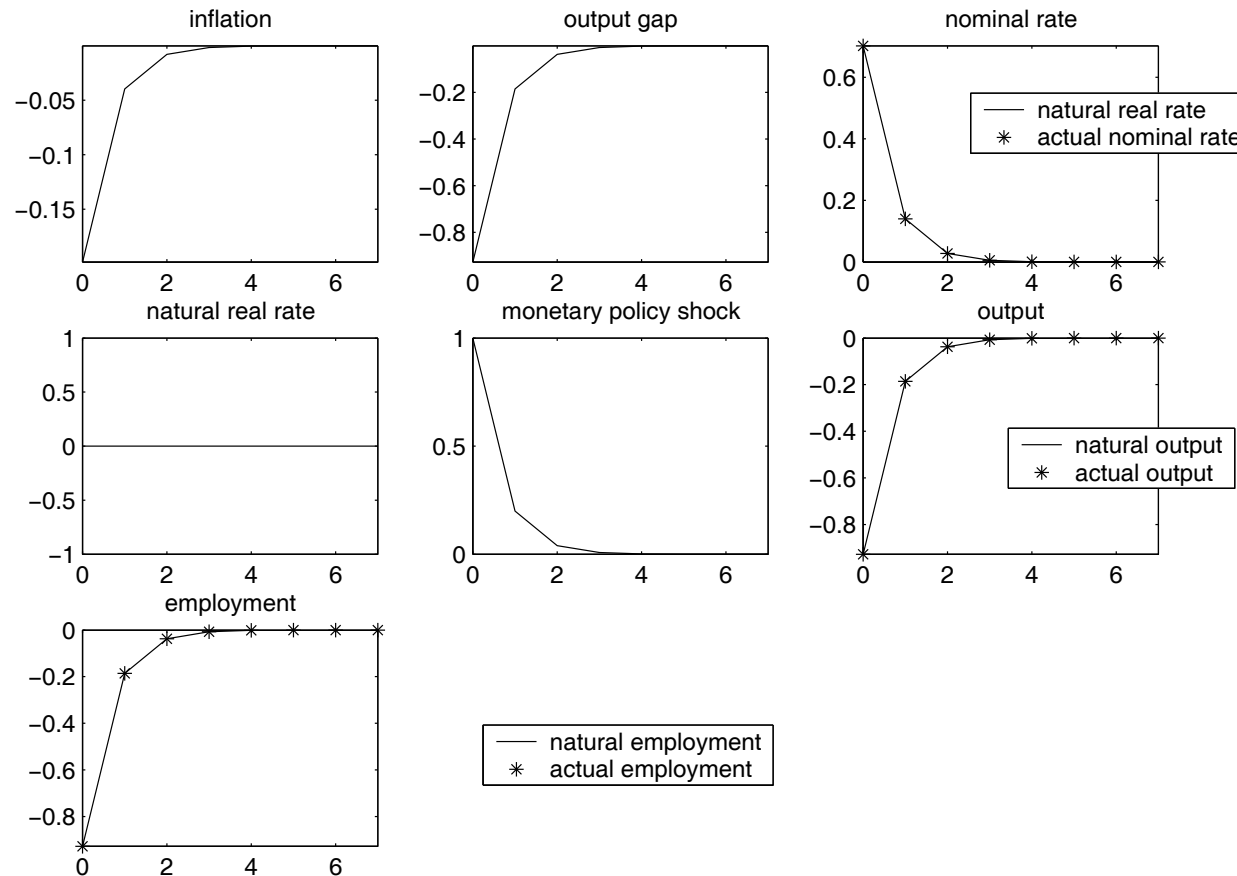

Dynamic Response to a Preference Shock

- Under policy rule, interest rate not increased enough.
  - This encourages consumption above what is needed for the zero-inflation equilibrium.
  - The extra demand drives up output gap, inflation

## Examples with Sticky Price Model ...

Dynamic Response to a Monetary Policy Shock

- Monetary policy shock drives up the interest rate
  - High interest rate discourages current consumption
  - Output, output gap and employment fall
  - Fall in costs causes inflation to drop.
